Mr DAVID GREIG'S *Clinical Observations on the Surgical Pathology of Bone*[2] is apparently the first book published in this country in which the theory of ossification associated with the names of Leriche and Policard is accepted in its entirety In a preliminary chapter the author expounds the new theory in detail, in subsequent chapters a number of selected examples of disease of bone are described in illustration of the application of the theory As the title indicates, the method of exposition is clinical, the history of each case and the circumstances and details of the treatment employed are recited, and from these the changes which necessarily follow in the bones are deduced and illustrated in a number of very fine photographs No better manner of approaching a subject in pathological anatomy could be conceived, and it is remarkable with what facility even the minutiae of the bone changes are explained by the aid of the new theory It has hitherto been considered that ossification may occur in two ways by the action of osteoblasts or by "metaplasia," by which is meant the direct conversion of adult fibrous tissue into bone without the intervention of osteoblasts According to the new theory bone is never produced in either of these ways, that is to say, osteoblasts are not bone producers, and connective tissue cannot be converted into bone without first being de differentiated in the direction of embryonic mesoderm, from which a re differentiation into osseous tissue becomes possible The latter is held to be the one and only mode of ossification, and in order that the re differentiation into osseous tissue shall occur two factors are considered to be essential a local excess of calcium to draw upon, and hyperaemia, which, by its rarefactive action will reduce the calcium to a soluble form Given these two factors, it is held that the differentiating tissue will assume the form of osseous tissue An example will illustrate the working of the theory In adhesions or scar tissue it is not infrequent to find a deposit of calcium, caused, it is supposed, by defective metabolism, in rare cases, whether from irritation of the crystals of calcium or from some obscure cause a vascular reaction is induced, capillaries grow inwards into the scar from the periphery and, in combination with the existing irritation, cause a de differentiation of the tissue elements, while at the same time the associated hyperaemia brings about a solution of the calcium In the presence of the local excess of soluble calcium the differentiating tissue will, it is held, develop into bone, and not into fibrous tissue The conditions are somewhat different where bone is in question instead of scar tissue, because there is already a local excess of calcium to draw upon, but the principle is the same in both cases Pathologists will, perhaps, be ready to accept this theory as a modification of their conception of metaplasia, but probably they will be less willing to relinquish the idea of a dual mode of ossification, and for this reason—that the local excess of calcium which forms such a prominent feature in the new theory does not appear to be present in all cases of ossification The huge masses of osseous tissue which are sometimes met with in ossifying tumours, in leontiasis ossea, and, in smaller amount, in osseous metastases in the lungs, are far in excess of the available local supply of calcium, and their production can hardly be explained on any other theory than that there exist cells whose function it is to extract the necessary calcium from the blood and utilize it in ossification If this view is correct, it would appear that ossification may occur under three different conditions there may be no local excess of calcium in which case ossification will be by osteoblasts there may be no osteoblasts in the tissue concerned, in which case ossification will take place in accordance with the new theory, or both osteoblasts and an excess of calcium may be present, when either or both modes of ossification will be available The subject deserves the attention of pathologists, and Mr Greig's book will be found of great assistance in gaining a comprehension of the problem involved

DIAGNOSIS AND TREATMENT OF BRAIN TUMOURS

Dr ERNEST SACHS of St Louis has done neurological surgery a service by publishing a work of reasonable size in which he sets forth a concise account of the modern approach to the surgery of brain tumours[3] The author does not belong strictly to any particular school, and his book, which is distinctly a personal one, is dedicated jointly to his wife and to Sir Victor Horsley It is not purely a book of operative surgery for it contains much more than that—pathology for example—with a useful description of methods of diagnosis both ancient and modern The appearance of the word diagnosis' in the title of a book written by a surgeon is significant, for there are even to-day those who decry strivings towards independence in this particular field, forgetting apparently that a parallel autonomy has been achieved in most other branches of surgery, often after a long struggle Complete independence must not be unduly stressed, for team work is, of course, essential

After early chapters on anatomy and physiology, Dr Sachs passes on to methods of examination The section on defects in the fields of vision might have been expanded, although its brevity is balanced to a considerable extent as the book progresses by the introduction of perimetric charts and a discussion of their value regionally On the other hand, it would have been a service had the author emphasized that which it is quite clear he himself thinks—namely, that the taking of careful fields is one of the most important points in the examination of any patient suspected of an intracranial lesion The section on x ray examination is good, and the plates which illustrate this part are excellent (as are the plates throughout the whole book) The technique of ventriculography is described, but not in such detail as will prove a sure guide to those who have not already had some experience There is a good description, very well illustrated of the pathology of cerebral tumours followed by a discussion of the symptoms presented by tumours in the various regions of the brain This is greatly helped by the introduction at suitable places of many case histories The book closes with sections on operative technique following

in general that method of operating which we generally credit to Halstead, and which has been pushed to its logical conclusion by Cushing. This is practically the standard technique to-day, and is satisfactory, if slow.

Dr. Sachs's book is an enjoyable one to read, and will be helpful to all working in this field, though some may wish at times that out of his rich experience the author had set forth more clearly his mature judgement on technical difficulties. The book is primarily intended for advanced students, and among these we may include many who are already graduates. They are fortunate in having presented to them so well favoured a volume.

FORENSIC MEDICINE

Professor SYDNEY SMITH'S *Forensic Medicine*[4] has now reached a third edition, and this within the short space of six years. While it adheres in general to the lines of previous editions, the text has in places been revised and new cases and illustrations introduced, the whole being welded into a well-balanced book, not too long and diffuse for a student to learn his work from, yet so full and complete that it will be retained by him, after qualification, as a reference book. The author draws attention in the preface to the revision of the section on insanity. After observing that the subject of unsoundness of mind cannot be treated adequately in a work of this size, he goes on to state that he limits himself to such aspects of insanity as have a medico-legal bearing; yet in the text an attempt is made to give a brief summary of the more common types of insanity, with which the student is already familiar from his lectures on mental diseases, but practically no mention is made of the mental cases which are the daily problems of any police surgeon in a large city, and only a very brief summary is given of mental defect, a condition met with daily in courts of summary jurisdiction. This section of the book could be rewritten with advantage. Apart from that, the general text is of a very high standard. The section on toxicology is clear and adequate, though now that poisoning by lysol has become so frequent we would like to see the direction to pass a stomach tube and wash out the stomach expanded and qualified; newly appointed house-surgeons sometimes do not appreciate what they are attempting to carry out. The book makes easy and interesting reading, is well illustrated, and the advice given is clear and sound. The student or practitioner will find it an excellent investment.

APPLIED PHYSIOLOGY

A new edition of Professor SAMSON WRIGHT'S *Applied Physiology*,[5] the fourth since 1926, hardly needs an introduction to medical readers. But there may still be students either too young or too old to have heard of a work which has established itself as the common prayer book of those wanting to understand the gospel of the higher medicine. That a fourth edition of a volume costing 18s. can be brought out so soon after the last is proof not only of a good book, but also of the fact that the significance of physiology in the service of medicine is becoming more and more appreciated. Dr. Langdon Brown drew attention to the importance of their relationship when he wrote his book, *The Physiological Principles of Treatment*. "Samson Wright" might almost be entitled "The physiological principles of diagnosis." The correlation of physiological and pathological processes is made clear by the application of physiological facts to clinical pictures. The physical signs of various diseases are explained in terms of disordered physiological function. With these ideas constantly in mind the student is taught to regard disease processes, not as pathological entities, having, so to speak, a textbook existence of their own, but as disturbances of the normal physiological equilibrium of the body.

A great part of the new matter in the book is concerned with recent knowledge of the ductless glands, including information on the active principle of the adrenal cortex, adrenaline apnoea, the conditions regulating adrenaline secretion, the relation of the pituitary to parturition, and on hyperinsulinism. The physiology of the sinus caroticus, the control of emotional movements, the chemistry of muscular contraction and heat production in muscle, and biological oxidation are subjects about which fresh information has been added. Several new figures have been supplied, and by the deletion of old material the size of the book has been unaltered. Professor Samson Wright is to be congratulated on worthily maintaining the standard he has set himself.

GLYCOGEN

As far back as 1885 Dr. A. BRAULT began a series of publications concerning glycogen and its metabolism, and he has now collected these into one volume, entitled "Glycogen in the Development of Tumours, etc." Abandoning any strict chronological order, he has set out his papers in six main divisions. The first two deal with glycogen formation in tumours, which entails a preliminary comparison between the development of tumours and the granulomata ("infectious neoplasms"). From this the author moves on to discuss the role of glycogen in the human embryo and in the invertebrates, protozoa and the lower vegetable species. These studies occupy two more sections, and in the fifth are found discussions of certain pathological problems concerning glycogen—in cirrhosis of the liver, in certain medico-legal aspects and in the diabetic kidney. In a final section Dr. Brault builds up his theory of the role of glycogen in nature on the basis of the facts set out in preceding chapters. As he sees it, glycogen formation is not an exclusive function of the liver or muscles, but is a part of general nutritive processes. Tissues which have lost the power of glycogen function after attaining full development can regain that power, according to the author's views, whenever demands of nutrition or growth require it. To follow all the arguments in support of this it is necessary to study closely a well-presented case, beautifully illustrated by numerous diagrams, but lacking, as is usual in French monographs, any sort of index.

NOTES ON BOOKS

The Thyroid and Manganese Treatment: its History, Progress and Possibilities[7] sets out in some considerable detail Dr. HERBERT W. NOTT'S views on this important question of preventing and controlling disease by systematic education. Inspired by Sir James Mackenzie's encouragement of the general practitioner to take advantage of his opportunities for advancing medicine, Dr. Nott's victim of intestinal disease necessitating a severe operation, and impressed with the importance of thyroid conditions and alimentary toxaemia, Dr. Nott has now collected the results of some ten years' work. He noticed that in some cases thyroid treatment was without effect, and, following McCarrison's [illegible]

)rded, and the progress and modifications of the treat-
it, which incidentally have been published since 1925,
here placed before the reader Dr Nott must be
ıplimented on his industry and perseverance

he second edition of Dr S A Loewenberg's very
ıprehensive work on *Diagnostic Methods and Inter-
tations in Internal Medicine*[1] appears less than two
rs after the first, and without being radically altered
ertheless shows signs of careful revision throughout
v material has been incorporated dealing with the
line blood supply and innervation, with massive pul-
nary collapse, with coronary thrombosis, hyper- and
o tension, with certain of the blood diseases, and with
interpretation of certain findings in the cerebro spinal
d In connexion with this last section, too much
ortance is perhaps attached to the sugar content of the
d in contrast to the three lines with which the chloride
tent is dismissed, without even the mention of the
mal figure It is impossible, however, to find more
n a few minor faults of this kind in the book, and
those who failed to make its acquaintance on its
: appearance it can be confidently recommended in
new form The very large number of illustrations are
eature of the book, and throughout the relation of
sical signs to pathological conditions is well stressed
diagrams and photographs The index of over fifty
es facilitates easy reference, while the final chapter on
hysical examination as applied to industry, life
ırance, health preservation and the detection of
ingering" contains a vast amount of valuable practical
wledge

Ir A H Sanford has thoroughly revised the well
vn *Clinical Diagnosis by Laboratory Methods*,[2] by the
Mr J C Todd (professor of clinical pathology in the
versity of Colorado), the seventh edition of which has
been published Very little alteration has been found
essary in the general appearance of the book and the
ıter part of the descriptive matter but less commonly
d methods have now been omitted in order to provide
ce for more modern procedures, such as the cultivation
ubercle bacilli, Fairhall's method for the determination
ead, and the more recent work of Folin, besides allow
fuller accounts to be given of certain tests previously
:ribed more briefly Allowance being made for the
ewhat different conditions on the other side of the
ntic, this book will be of practical interest to those
cerned with pathological laboratory methods in Great
ain

second edition of *A Synopsis of Pharmacology*[3] by
late Dr D Cow, has been produced by Dr G N
ERS The synopsis deals with all the important drugs
alphabetical order, and describes briefly their chief
rmacological actions It is intended for the use of
lents, and should be found useful for those who desire
ondensed summary of the subject for purposes of
sion

1 his little work entitled *Clinical Aspects and Treat-
it of Articular Rheumatism*[4] Dr L Schmidt empha-
s the seriousness of the condition, and gives a concise
ount of the etiology clinical symptoms, and treatment
he diseases based on his experience at Pistany

Read's *Introduction to Organic Chemistry*[5] is worthy of recommendation to all students first entering on the study of this subject The various classes of compounds chosen for illustration of the basic principles of organic chemistry are those best calculated to prepare the way for further specialized study These are described in clear and simple language together with details of the procedure necessary for practical performance by the student The book is very well suited for beginners who are afterwards to follow organic chemistry in its biological application

PREPARATIONS AND APPLIANCES

An Illuminating Tongue Depressor

Dr F W Cope (Leeds) writes

For some time past the want of a proper apparatus for examining the tonsils and pharynx has been acknowledged especially for children The preliminary efforts to fix the head in position adjust the light and press down the tongue with the handle of a spoon or wooden spatula excite the child to such an extent as to make the examination almost a major operation Happily this is now a thing of the past with the electrical apparatus illustrated here in

The sliding spatula is adjusted to the right position and the light is switched on it is shown to the child who is at once interested and is asked to open his mouth The tongue is depressed and a second only is required to see all that is necessary The torch is removed and the glass sheath and tongue depressor are immersed in boiling water and sterilized in a few minutes then wiped with a clean towel or handkerchief The torch is reinserted and the tongue depressor retracted on the making a portable package for the pocket The light is easily switched on and off and the dry battery will last some time

Two leading gynaecologists have spoken well of this apparatus for vaginal examinations and favourable reports have been received from medical men for throat work The facility of examination the saving of time the psychological effect, especially on children and the perfect sterilization combine to produce an instrument which all medical men should find very useful in everyday practice

This apparatus is manufactured by Reynolds and Branson, Ltd 13 Briggate Leeds

THE EYESIGHT OF MOTOR DRIVERS*

BY

N. BISHOP HARMAN, LL.D., F.R.C.S.

SENIOR OPHTHALMIC SURGEON, WEST LONDON HOSPITAL

The coming into force of the Road Traffic Act, with its requirement of a declaration on the part of the applicant for a licence of a certain standard of vision, has aroused little comment, either by way of commendation or criticism. It would appear that the regulation was in some sense a reaction to a popular demand caused by an allegation that "the vast majority of road accidents are due primarily to defective eyesight on the part of the pedestrian or driver." Whether or not the regulation will be effective in reducing the incidence of motor accidents we shall never know, for there is no evidence of the truth of the allegation of the dominant influence of bad sight. Accidents known to be due to bad sight do occur, but they appear to be rare. I have searched my records of bad-sighted patients, and find in several hundred only three such cases. A man with advanced chronic glaucoma stepped in front of a moving car and was killed. A woman, nearly blind from senile cataract, did the same, and was severely injured. A man nearly blind from optic atrophy drove his own car in a rural district for some years in safety—with a child on his knees to direct him!—but he eventually came to grief.

A Conflict of Evidence

Evidence given to the Select Committee of the House of Commons was in sharp conflict. For the R.A.C. it was said that the majority of road accidents appeared to be "unavoidable," and were due in general to a lack of road sense rather than to a lack of competence. The traffic advisor to the Metropolitan Police, admitting the relative freedom from accidents of the taxicab driver, who is subjected to comprehensive tests, considered that "in many cases danger does not arise from want of competence, but rather from want of consideration and undue trust in the driver's competence." For the London General Omnibus Company it was said that the bulk of accidents "arise out of the fact that there is a lack of mental alertness in the particular circumstances in which the accidents occur."

The only witness who urged the necessity for sight tests came from the Cyclist Touring Club. He said "far too many people are driving motor cars now whose sight renders them very dangerous." But on what facts this opinion was based we do not know.

One real piece of evidence of importance was given by the London General Omnibus Company. In the years 1927 and 1928 the company received 61,000 applications for employment as drivers. From these, 3,936 candidates were selected for examination with a view to employment. Only 56 per cent. of those selected passed the medical examiners, and of the 44 per cent. rejected about four-fifths were not aware of having any physical disability whatsoever, and were much surprised at their rejection. Of the 56 per cent. of the selected list who passed the medical examination, 90 per cent. passed the competence test for driving, and were placed on probation for a period of three months. Of these, a further 2 per cent. were, during the probationary period, found unsuitable to drive, as they "at once fell into accidents, and therefore showed that they had not got that balance of mind which is necessary to be a safe driver upon the roads." This means that only 30 per cent. of the superficially suitable candidates were actually accepted as drivers after test. (It will be noted that the evidence does not differentiate between the various forms of physical unfitness.) In 1928 the London General Omnibus Company had 100 fatal accidents, but in no case was any blame attached to the drivers in the course of the inquests. Of the fatal accidents 60 per cent. were found to be attributable to pedestrians, 26 per cent. to cyclists and motor cyclists

Standards of Vision

The problem has been considered in many countries. Most Continental countries, and many of the States of the United States of America, have passed laws requiring certificates of medical fitness, particularly as regards eyesight. Some are very severe—for example, German

Only those individuals are suitable to drive motor cars whom the visual acuity is over 1/2 in one eye, with or without correction, and reaches a minimum of 1/6 in the other eye, provided also that the field of vision is normal, and that examination has eliminated the question of any illness not recognized as causing weakness of sight. Persons whose visual acuity in an eye is less than 1/6, or completely lacking may be passed if that condition is at least of two years' standing and the other eye has an acuity of at least 2/3 with correction. Such cases require the certificate of an oculist. Persons suffering from diplopia, aphakia, or hemeralopia are unfit to drive motor vehicles.

We may be inclined to the opinion that the German rule is better than the English rule. Ability to read the number plate of a motor car at a distance of 25 yards (between 6/18 and 6/12) without regard to field of vision must be insufficient for the purpose desired.

There are certain possible reactions from the English regulation. The issue of a driver's licence to an applicant who can properly make the required declaration is in some sense a guarantee of his fitness to drive. It is true that no such guarantee is given, but there will undoubtedly be a tendency to hold that it is implied. The legislature has taken this risk, notwithstanding advice tendered to it by experts that the standard was inadequate. Ophthalmic surgeons, therefore, must strive to spread the knowledge of what in our opinion is good and sufficient vision for road users.

Safe progression for driver and walker in ordinary daylight demands that the sight should have a third quality: visual acuity, field of vision, and binocular vision. Obviously a driver must have acuity sufficient to see a pedestrian, and to see him well enough to be able to judge of his probable actions. For such a purpose the 25-yard standard is probably quite sufficient. But the fact that this criterion alone is recognized belittles other factors in vision, which for locomotion are of far greater importance. Without a good or sufficient field of vision the fullest visual acuity is useless. There is no one who has not known patients with vision equal to 6/6 who were, by reason of their limited fields, blind for economic purposes. Freeland Fergus, in a paper published in the *British Medical Journal* (1928, i,), stressed the necessity for a good field of vision, even went so far as to assert that form vision was relatively unimportant for general purposes. His emphasis on the need of a good field was right, though his belittlement of acuity was wrong. Acuity necessary, but for locomotion the field is more so. Experience shows that persons with a 20 degree field of the periphery of the field of vision find that in walking they are liable to bump against objects such and door posts; they do not see objects which beside them. Such a limitation as this would apply in a high degree to the driver of a fast-moving

Binocular Vision

The need for binocular vision is a moot point. Personally I am sure that it makes for a safer and safe driver. By binocular vision we

* A communication to the Section of Ophthalmology at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

of the position and size of objects and our relation to them. It is true that this can be found to some extent by the swift and unconscious movement of the head, and the appreciation of the parallax. But this faculty is not developed easily, and the evidence gained from it is not always reliable. Medical officers of the R.A.F. hold that defects of binocular vision are in the main responsible for bad landings, which account for a large proportion of flying accidents. In somewhat the same fashion car drivers who frequently get into minor scrapes owe their lack of judgement to defective binocular vision. I know that there are cases of one-eyed men who have done well. Hinchliffe was one-eyed, and a great airman. I read recently that Wiley Post, who flew round the world in nine days, is a "one-eyed Red Indian." An even more remarkable feat was performed by the Italian motor car driver in the Irish Grand Prix race this year. A stone hit his goggles, and splinters cut his eyeball. After a rest he pluckily resumed driving in spite of being bandaged over one eye. To drive a car at 100 miles an hour in such a state was no mean feat. Also I know of a one-eyed surgeon who has driven for years with safety in London traffic.

Notwithstanding these exceptions I do not like the one-eyed driver; I should not employ one myself, and would not drive with one eye obscured. I have tried it, and I did not like the experience. I think that much of the difficulty which drivers find in reversing is due to the fact that during that driving they are one-eyed. I am sure that with our rule of the road a man blind of the right eye and with a Wellingtonian nose is not safe. I think that a fair measure of the safety of the one-eyed can be gained by his ability to play tennis. Fast ball games require swift judgement of positions; those with good binocular vision are able to excel, those with bad binocular vision or none are usually failures. Golf is in another category; the one-eyed man can play the game almost as well as the man with perfect binocular vision.

Defects of muscle balance likely to cause diplopia in states of fatigue will require caution. In lower degrees of defect the driver will not be likely to be unsafe, but he should be cautioned against lengthy drives, or driving when in poor health. In higher degrees of defect with frequent symptoms of diplopia there will be added risks. It is certain that constant diplopia should be a bar to driving unless this can be done with one eye partly obscured with the Chavasse glass.

Night Driving and Light Sense

The reliability of the modern car tempts people to use it as a general conveyance, so that night driving is growing much more common. In this connexion the light sense becomes of special importance. It is common to find that myopes dislike night driving, for the very form of their lenses reduces the light that enters the eye.

It is comparatively easy to determine whether a person with a doubtful light sense is safe or not. It can be judged by the use of the perimeter. If the peripheral field be mapped out in good daylight, and then again after the adjustment of the window blinds so as to reduce the illumination to one-tenth of the full light, the excessive reduction of the field of vision in those with a defective light sense will be manifest. Subjects of these defects may be safe drivers in the daytime, but at night they are dangerous. These persons, and especially the high myopes, recognize the defect and avoid night driving.

Colour-blind Drivers

Defects of colour vision should not constitute any disability for driving, either day or night. But the growing use of coloured signal lamps at road crossings has introduced a real difficulty for the colour-blind. Signal lamps of red, yellow, and green are springing up everywhere. A mistake in reading one of these signals may bring the colour-blind driver into conflict with the police, and possibly into collision with other drivers or pedestrians. It is surprising that, despite warnings the authorities have had in this relation, they have not seen fit to adopt the more simple and safe signals which depend upon form rather than colour. A horizontal bar of light would everywhere be recognized as a sign to stop, a round light would indicate the need for caution, and a vertical bar of light would indicate a clear road. Such a plan would follow the long-established precedent of the semaphore signal, and could not lead to confusion.

Other Factors in the Problem

Such a sketch of the sight the motor driver should have gives a very poor view of its complexity. Nor does it touch upon the interrelation of sight and muscular co-ordination—foot, hand, and eye—of the driver. Nor does it hint at the overriding power of nerve control suggested in the term "reaction time"—that power of response which makes two persons who show a general equality in equipment so far apart in capacity. Many accidents arise from a defective reaction time. Perhaps as many are due to visual or cerebral anaesthesia, because the mind behind the eyes is far away from the road—"seeing, they shall see, and shall not perceive." This visual anaesthesia, or wandering attention, has caused the death of not a few drivers and walkers, and there is no cure for it. Again, all our reactions vary from time to time, so that a test one day may be valueless on the next. Ill-health, unwise indulgence, and fatigue (such as is caused by too long driving) produce wide variations in "reaction time." One driver is made jumpy, so he handles his car injudiciously, and it skids into a crash; another becomes too slow in the uptake, and he runs into a collision. These changes due to fatigue become most manifest on entry into a large city, so that a momentary rest before proceeding into crowded streets is a wise precaution.

Practical consideration will inevitably lead to a double standard of fitness for drivers. Public utility and transport companies and taxicab proprietors must demand a proper medical examination of the eyes of their employees. They are responsible for their safety. Also accidents do more than damage cars; they hold up vehicles during the slow process of repair, and insurance rarely covers that loss. A strict examination is justified for these drivers, for they have to drive in all weathers, and both day and night, so that minor defects may become material. Private drivers will in time learn that it is wise for their own safety and peace of mind to gain the assurance of sufficient sight for the driving of the modern speedy car; and if a more liberal interpretation of standard be allowed to them it can only be on the understanding that their driving is intermittent, and not undertaken when conditions are likely to be adverse.

The Council of Epsom College will shortly award two "France" pensions of £30 a year to medical men. Candidates must be not less than 55 years of age, and their income, independent of any allowance from the College or from the Royal Medical Benevolent Fund, must not exceed £100 a year. The Council will also award one "Grewcock" pension of £70 a year. In this case there is no limitation as to age, but candidates must be legally qualified medical men who have retired from professional work, and who, in the opinion of the Council, are in need of the pension. There is the same income limit as in the case of "France" pensioners, and special consideration will be given to the claims of candidates having association with Worcestershire, Lincolnshire, or Carmarthenshire. Forms of application should be obtained forthwith from the secretary, Major W. L. Giffard, O.B.E., 49, Bedford Square, W.C.1.

British Medical Journal

SATURDAY, NOVEMBER 7th, 1931

ENCEPHALITIS LETHARGICA

It is twelve years since Professor Constantin von Economo, whose death we had to announce last week, published in Vienna his clinical account of thirteen cases of an unfamiliar disease to which he gave the name encephalitis lethargica; and now, in the English edition of his *Encephalitis Lethargica: Its Sequelae and Treatment*[1] we find gathered together for English readers the fruits of his subsequent experience as professor of psychiatry and neurology in the University of Vienna. His object was "to present a survey of the complex features of encephalitis lethargica from the clinician's point of view." He begins with a brief review of the discovery and naming of the disease (including a plea for the retention of the term encephalitis lethargica, rather than that of encephalitis epidemica), of the epidemiology of recent epidemics, and of previous outbreaks of epidemic disease associated with lethargy or somnolence. From a consideration of these events Professor Economo hazards the opinion that the disease in its epidemic form may disappear and remain dormant for some considerable time. The acute form of the disease is then discussed at some length, and three basic syndromes are described: (1) the somnolent-ophthalmoplegic, in which group most of the sporadic cases are included; (2) the hyperkinetic group of cases which show unusual toxicity and seldom occur in sporadic circumstances, but frequently in association with influenza outbreaks; and (3) the amyostatic-akinetic form of encephalitis which often precedes the Parkinsonian state. A fourth group includes various atypical forms not infrequently seen, such as cases with cerebellar symptoms, neuritic cases, epidemic hiccup, and others, together with the rarer mono-symptomatic types. Prognosis, in the author's opinion, should always be considered in reference to the character of the prevailing epidemic (*genius epidemicus*); thus the mortality and incidence of sequels are high in hyperkinetic epidemics and comparatively low when the somnolent-ophthalmoplegic type predominates, while the amyostatic cases are less fatal in the acute stage, but more prone to sequels. Intravenous injection of iodine in large doses is described as the classical treatment in acute cases, and this apparently secures better results than have been attempted or achieved in this country.

In his discussion of the morbid anatomy of both acute and chronic encephalitis Professor Economo insists that the primary process of degeneration is the destruction of the ganglion cells, perivascular infiltration being a secondary reaction. His post-mortem studies of Parkinsonian cases support the opinion now generally held that the virus of the disease persists in the chronic forms, and a doubt is expressed whether, in such cases, it is ever eliminated from the central nervous system. Others share this doubt, but there is some clinical evidence that, though present, the virus may remain inactive for a considerable time. Thus Professor Arthur J. Hall in his Schorstein Memorial Lecture on "Chronic epidemic encephalitis," which we publish in our opening pages this week, is now able from his own extensive experience of the disease, including 325 cases of Parkinsonism, to speak more hopefully about the prospects of patients who may suffer from this form of chronic encephalitis. It is comforting to learn that over 50 per cent. of Professor Hall's Parkinsonian patients, with an infection of at least seven years' standing, are able to lead more or less normal lives; some, even in the eleventh year of infection, appear to be engaged in unusually interesting and active pursuits, and "quite a number" have married.

Among other findings, the fact that the pituitary gland shows no change[-y extra]idered significant, in view of the role sometimes assigned it in the derangement of the sleep function. Dealing with differential diagnosis Professor Economo considers that, despite the clinical and pathological differences between cases of encephalitis lethargica and cases of influenza, these two diseases are, in some as yet unknown way, epidemiologically related. He believes that, clinically, post-vaccinal encephalitis is distinct from encephalitis lethargica, and "should not be forced into closer relation with it." The sequels of the disease are considered under two groups: the first comprises residual states (in which, after the resolution of focal symptoms, some symptom of the acute attack remains to mar an otherwise complete recovery), and protracted states of convalescence, which include relapses, intermittent progressions, and certain psychasthenic states; the second group mainly comprises Parkinsonism and the conduct changes in children here called juvenile pseudo-psychopathic. It is the cases belonging to this second group which stand out significantly, and occasion pessimism as regards treatment. Iodine therapy is again chiefly recommended for chronic cases in the first group, though the author admits that improvement, where it occurs, is often not maintained; treatment by diathermy is described in some detail. Scopolamine is regarded as the most important remedy in the symptomatic treatment of Parkinsonians, but, beyond a reference to the use of bulbocapnine, little is said about the treatment of post-encephalitic children.

In his general review Professor Economo suggests that there is some compensation for the present helplessness as regards the treatment of encephalitis [illegible] the fact that the study of the disease has revolutionized our conceptions of pathological and normal mechanisms. It has shown, for example, that many so-called functional disturbances can now be explained on neuro-anatomical—that is, [illegible]. Once more, too, attention may be [illegible]

[1] *Encephalitis Lethargica: Its Sequelae and Treatment.* By Constantin von Economo. Translated and adapted by K. O. Newman, M.D. Oxford Medical Publications. London: Milford, Oxford University Press. 1931. (18s. net.)

rofessor Hall's lecture, and in particular to his very nteresting arguments about the oculogyric crises of ost-encephalitis and their probable relation to sleep isorders. Professor Hall's observation that in these rises the eyes are not always rolled upwards, but ssume various positions, led him to investigate the osition of the eyes in other subjects during deep sleep. was found, again, that in 46 per cent. of the 206 ases tested the eyes were not drawn upwards, but ccupied various other positions; this shows that the octrine on this point handed down by Sir Charles Bell ore than a century ago does not embody the whole uth, and should be modified in accordance with arling's teaching that "the eyes during sleep may ccupy any position."

Professor Economo's latest contribution to the lore of ncephalitis lethargica will be studied with profit by ose who are now called upon to recognize and treat is affection; moreover, this clinical picture of the isease, brushed in by a master hand, may prove of qual value as a guide to future physicians who may, n their turn, be confronted with cases of an unfamiliar idemic disease. It should be added that Dr. Newman, y his excellent translation, has done much to ensure or the English edition that welcome by English and merican readers which the distinguished author esired.

NTERNATIONAL VITAMIN STANDARDS

ast week we dealt with the new decisions made by the ermanent Commission on Biological Standardization, nder the League of Nations, concerning certain import nt serums and bacteriological remedies [1] We publish is week at page 862 an article dealing with recom- iendations for the adoption of international standards nd units for four of the known vitamins These ecommendations were made by a conference, meeting t the same time in London, of leading investigators rom different countries, and were adopted without odification by the Permanent Commission Professor dward Mellanby was chairman of the conference, and Dr. Harriette Chick and Dr Aykroyd of the Lister nstitute acted as secretaries The other members were 'rofessor J C Drummond (London), Professor v. Euler Stockholm), Professor Fridericia (Copenhagen), Pro- essor Jansen (Amsterdam), Professor McCollum Baltimore), Professor Poulsson (Oslo), Mme Randoin Paris), Professor Scheunert (Leipzig), Dr. Seidell Washington) Professor Steenbock (Wisconsin), and Professor Windaus (Gottingen). The League Health Organization in setting up the conference, followed its ractice of choosing the members with a view to their xpert knowledge of the subject, and not on a basis f national representation; but we think that there will e no doubt of the widely representative character of he conference, or of the authority given by its dis- inguished membership to its decisions on any matter oncerned with vitamins.

[1] *British Medical Journal*, October 31st, 1931, p. 809

The members of the conference are to be congratulated on their unanimous agreement with regard to the standards and units to be adopted for so many of the vitamins There must have been many points of detail, or even of principle, on which each expert had a well-grounded confidence in his own special methods Very wisely they concentrated their effort on the task of finding stable standard preparations which all could accept, and of agreeing upon units which could be defined in terms of these In so doing they followed the practice introduced by Ehrlich in 1894 for diphtheria antitoxin, the first therapeutic agent to have its dosage accurately indicated in units of biological activity adopted by the Permanent Commission in dealing with other substances, and abundantly justified by experience. It is probable that few of those who use remedies of this class daily in their practice realize how much of the ease and confidence with which they adjust the dosage to the needs of the case is due to the international action which the Health Organization of the League has promoted and made effective It was the intervention of its Permanent Standards Commission, in 1923, which averted the confusion threatened by a whole series of competing "units" of insulin—"physiological units," "clinical units," "rabbit units," "mouse units"—and based the notation of insulin activity, once and for all, on a stable standard and a single unit defined in terms of it, and now used by the whole world

The history of the dosage of vitamins shows many points of similarity to this The conscientious manufacturer, whether making concentrated preparations of the different vitamins or buying materials such as cod-liver oil for incorporation in medicinal preparations or foods, wished to know and to indicate the specific activity of what he bought or sold Competing and varying units, based on different types of biological test, had been produced by the need for some kind of notation. Some pharmacopoeias had already attempted to base standards for cod-liver oil on prescribed animal tests Even if a perfect, world-wide uniformity of the animals and the diet used in such a test could be secured, which is hardly credible, a unit based on it would become obsolete, with consequent confusion of scientific records and practice, whenever research produced a new and better test. In the case of vitamin D, action was peculiarly urgent, in view of the evidence that overdosage may cause serious harm More than a year ago the Medical Research Council issued a provisional stable standard for this vitamin, and recommended the general adoption in this country of a unit defined in terms of it The Council's action was endorsed, not only by the prompt compliance of all concerned in Britain but by a large number of requests for the standard from research workers and manufacturers in other countries It has again been endorsed by the conference in recommending this standard and unit for formal international adoption The conference similarly defined units of vitamin A based on a standard of purified carotene, and of vitamin B_1, based on

Professor Jansen's dry adsorption-product. In the case of vitamin C, Nature has saved much trouble by providing a standard in every fruiterer's shop; but the simple agreement to adopt the activity of one definite volume of fresh lemon juice as a unit should bring a new harmony into scientific records, as well as into practice and commerce.

It should be noted that the conference wisely made its recommendations effective for not more than two years in the first instance, foreseeing the possibility that a purer standard, for one or another of these vitamins, might easily become available, and provide a better basis for definition of the unit, without change of its value. In the case of vitamin D, research has already advanced more quickly than the conference can have anticipated. In a letter in last week's *Nature*, Askew, Bruce, Callow, Philpot, and Webster, working in the National Institute for Medical Research, under the leadership of Dr. Bourdillon, describe a further big stage in their purification of the crystalline preparation of vitamin D, which they have named "calciferol"; its properties raise the question of its identity with one of the two crystalline antirachitic preparations ("vitamin D_1," and "vitamin D_2"), which have just been described by Windaus and Linsert in Germany. "Calciferol" has now an activity approximating to 40,000 international units in 1 milligram; and there can be little doubt that the isolation of a perfectly pure antirachitic vitamin, in one or other of the laboratories engaged in the attempt, is well within sight, if not already substantially achieved. Before long the unit of vitamin D may be the activity of an exact weight of a pure substance.

Meanwhile, now that the units should have the same meaning in all countries, comparable clinical data ought soon to be available for determining the effective and safe dosage of each of these vitamins in its different applications. The League and the laboratories have done their parts; the practical outcome is in the hands of clinical medicine.

PLASMOQUINE TREATMENT

Since the first observations on the treatment of malaria cases by plasmoquine, carried out by Mühlens in 1926, this preparation has been extensively tested in many parts of the world. Major Manifold, in a "Report on a trial of plasmoquine and quinine in the treatment of benign tertian malaria," discusses the use of this drug on a large scale among the troops in India.[1] After various methods of treatment had been tried in benign tertian malaria, it was noted that 0.04 gram of plasmoquine and 20 grains of quinine per diem for twenty-one days appeared to have given the best results in the prevention of relapses and in the avoidance of toxic symptoms. Altogether 3,213 cases of benign tertian malaria were placed on the above dosage, and 3,187 patients completed their twenty-one days of plasmoquine and quinine treatment. Temporary suspension of the drug for varying periods of time was necessary owing to the appearance of toxic symptoms in 21.4 per cent. of 1,298 British, and 10.2 per cent. of 1,915 Indian cases. In the great majority of instances the symptoms of toxicity—namely, abdominal pain, cyanosis, and digestive disturbances—were never severe, and were less frequent among Indian than British cases. The complaint of epigastric pain showed variations in its incidence in various hospitals, but it was concluded that severe pain and pain of prolonged duration was the exception rather than the rule. The onset of methaemoglobinaemia, as indicated by a blue tinge on the lips, gums, tongue, and finger-nails, was recorded in 56 British (4.3 per cent.) and in 13 Indian cases (0.67 per cent.). In 80 per cent. of these it appeared on or after the seventh day. The treatment quickly reduced acutely enlarged spleens, but the action on chronic enlargements of this organ is doubtful. Pyrexia responded more rapidly to treatment with plasmoquine and quinine than to quinine alone. There were no deaths due to plasmoquine, and it was concluded that this drug in the above dosage can be safely given to all classes of patients.

NOISE IN OXFORD

The amenities of academic life at Oxford have been badly encroached upon of late, and the charms of the place endangered. Goths who ought to know better build over beautiful old gardens, and from all quarters complaints are made of the vast increase of noise and vibration due to traffic. But the lovers of quiet realize that a passive attitude of suffering will not help them, and are determined not to be destroyed by excessive vibration without striking at least one blow in self-defence. The Master of Balliol recently presided over a meeting in Oxford Town Hall, convened by Dr. William Collier and others, at which it was decided to form the Oxford Noise Abatement Society. As the chairman frankly said, the authorities are sympathetic, but they seem to be oppressed with a feeling of impotence in this matter, and will welcome the advice and support of men of science, for which reasons Professor A. M. Low and Sir Maurice Craig had been invited to address the meeting. In the resolution subsequently passed the object of the society was stated to be "co-operation with the local authorities in diminishing the unnecessary speed, noise, and vibration of motor traffic in our streets." There is no doubt that much might be done by enforcing existing laws and regulations, notably that which forbids the use of unsilenced exhausts. Oxford is particularly exposed to the evils of traffic because the principal colleges and academic buildings are situated on, or close to, the main thoroughfares, and because the great residential district of North Oxford is built largely on the Banbury and Woodstock roads, two great highways upon which heavy lorries and fast and monstrous motor cars thunder along, by night as well as by day. These noises, not in themselves pleasing, have their associations which render their repetition agreeable by force of association. The din of Bath, which Miss Austen thus feelingly described—"the dash of the carriages, the heavy rumble of carts and drays, the bawling of newsmen, muffin-men, and milkmen, and the constant clink of pattens"—gave no offence to Lady Russell, who welcomed it as symptomatic of "animation and cheerfulness," while to Anne Elliot it was [illegible]

nobody, we suppose, however anxious to respond to the slogan and "drink more milk," will associate the crash, bang, and clatter of the milk-can lorry with pleasurable sensation, nor the machine-gun fire of the motor cycle with anything more pleasant than a pneumatic drill. The needs of civilization, and the efforts of commerce to supply them, are at the root of the plague of noise; successful commerce implies elimination of waste and friction. Yet noise and vibration of other kinds are clearly wasteful, and often extremely deleterious to the machine. It is on this line of argument that the best hope of advance seems to us to be expected. In short, *noise does not pay*, and this fact has to be instilled by persuasion into the business man's mind, so that he may at length be enlisted in the ranks of the advocates of peace and quiet. Yet the question is complicated by the multiple functions of the average citizen. The man who hurries on a motor cycle along the Woodstock or the Banbury Road seeking the peace and quiet of his suburban home at evening gives little or no thought to other people's homes which he passes on the road. As long as noise was beyond exact measurement and definition the difficulties of legislation and regulation seemed insuperable; but this difficulty is now removed. In a recent article in these columns[1] we commented on a lecture on this subject given by Dr. Kaye at the Royal Institution. The measurement of noise on the spot, and the conviction of the offender caught in the act, is not yet so simple and easy as the detection and conviction of the street hawker whose weights are light; but simplification will surely come. *In coelo quies* seems to be an outcry of despair, and we may hope for a little quiet cheerfulness on this earth.

GLANDULAR FEVER

First described in a satisfactory manner by Pfeiffer in 1889, glandular fever has become more widely recognized as a clinical entity in this country in recent years through the writings of Dr. H. L. Tidy, and at the last meeting of the Section of Medicine of the Royal Society of Medicine this worker put forward his latest views on the disease. It will be remembered that a curious epidemic occurred, principally among adults, in 1930 in many parts of London and elsewhere, in which patients with an eruption resembling that of enteric or rubella subsequently developed glandular swellings and in many instances showed the presence in the blood of the peculiar mononuclear cells characteristic of glandular fever. Dr. Tidy's thesis is that this epidemic represented the full-blown type of glandular fever. He regards this disorder as an acute specific infective fever, with consecutive stages of invasion, eruption, and glandular enlargement, lymphocytosis developing in the course of the last stage. Other types are met with which can be traced from the full course by the omission or overlapping of various stages, and by the omission and overlapping of various features. Thus in children the second stage (eruption) and possibly the first are usually absent, forming the type of glandular fever most commonly seen in past years. Many points of difficulty in diagnosing this condition may arise, especially in the early eruptive stage. The rash sometimes closely resembles that of typhoid fever, and in the course of the discussion Dr. J. Mills described how, in certain cases encountered during a small outbreak of glandular fever in Reading, a positive agglutination to the "O" strain of typhoid organisms occurred. This makes the problem of the etiology of glandular fever a complicated one. Dr. John Bland, at the same meeting, described his attempts to transmit the disease to animals. Blood taken during the febrile stage, from human patients, was successful in producing a sort of glandular fever in rabbits, which was passed on to further generations by inoculation, and some strains of the "organism" are still being kept going. From the inoculation of glandular tissue he obtained only negative results. He is inclined to think that a protozoon is the causative organism of glandular fever. Several interesting points were raised by subsequent speakers. Is it a true lymphocytosis which occurs in the blood in these cases, or is it not more correct to say that all the normal white cells are decreased in number and a special immature type of leucocyte appears? Examples of glandular fever without these typical blood changes have been recorded, and indeed, in the 1930 epidemic, it was found that during the eruptive period a polymorphonuclear leucocytosis was the rule. Various suggestions for the treatment of the condition were made, such as the use of sodium nucleinate to stimulate leucocytic production and the giving of blood from patients convalescent from the disease. Dr. Tidy's summing-up of this part of the subject was emphatically against employing any method of treatment. Patients are more likely to get well if not interfered with. It was stressed that epistaxis is a very common feature at the onset of glandular fever, and the "sore throat" so frequent in children suffering from the condition is a swelling of the lymphatic tissue of the tonsils, without any definite inflammation, a point of help in diagnosis. That the "childish type" may occur in adults, and vice versa, is not excluded by Dr. Tidy's thesis, and indeed at the meeting Dr. Herbert J. Williams described his own experiences with an attack of glandular fever without the eruptive period. The fact that the Wassermann reaction sometimes becomes positive during an attack of glandular fever has also to be borne in mind in making a diagnosis.

THE VISION OF SCHOOL CHILDREN

The Board of Education has issued the report[1] of a special committee appointed to inquire into the problems connected with defective vision in school children. The members of the committee were: Sir George Newman (chairman), Dr. R. H. Crowley of the Board of Education, Dr. Dunstan Brewer, M.O.H. and S.M.O. for Swindon, Dr. J. J. Butterworth, M.O.H. and S.M.O. for Lancashire, Mr. Percy Flemming, consulting ophthalmic surgeon to University College Hospital, and Mr. Bishop Harman, consulting ophthalmic surgeon to the West London Hospital and oculist to the L.C.C. Education Department, with Dr. J. E. A. Underwood as secretary. The committee was directed to inquire into the factors in childhood leading to the development or aggravation of defective vision and squint. At the outset it found that there existed no sufficient data of what constitutes "normal" refraction for the child at different ages, so it sought to gather material for the

[1] Board of Education. Report of the Committee of Inquiry into the Problems connected with Defective Vision in School Children. London: H.M. Stationery Office. 1931. (6d. net.)

establishment of a standard or "basic scale" of refraction for each age group and sex. Special investigations of refraction were made by twenty-two observers, and the results of 2,625 cases were examined. The variations found were so great that tabulation was difficult. It was determined to record each case according to its greatest deviation from the normal, whether astigmatism or anisometropia was present. The results are set out in tables that are distinctly graphic, although made up of figures. Simple hypermetropia is by far the commonest condition of refraction met with in children of school age and under. The highest incidence is found to be 87.4 per cent. in the age group of 1 to 2 of boys, the lowest 53.1 per cent. of the 13 to 25 age group of girls. Hypermetropia of one dioptre tends to remain unchanged over a course of three or four years. Hypermetropia of two dioptres shows a tendency to decrease during two or three years. Higher degrees also tend to decrease. Generally speaking, the higher the degree of hypermetropia the more is the tendency to decrease, and, on the other hand, the higher the age group the less is the tendency of the hypermetropia to decrease—that is, the condition appears to be more stabilized as age increases. Of children with hypermetropic astigmatism it was found that the majority had from one to two dioptres; higher degrees were comparatively rare. Emmetropia was rare: in a series of 1,116 cases under the age of 5 there were only 14 emmetropes, and none below the age of 1 year. In the higher age groups the number increases, but without any steady progression. Above the age of 5 years the percentage was 5 to 6. There was some evidence to show that the emmetropic eye in the young child is often in a transition stage on the way to myopia. As with myopia, the incidence of emmetropia is so low in children under 5 because they have not had time to develop it. In the tabular analysis showing results of tests for myopia the striking feature is the rarity of cases of myopia in both boys and girls below the age of 5 among unselected children. As consideration passes to the higher age groups it is found that the incidence becomes greater, though the figures present no regular progression. The incidence and degree is rather higher in the girls than in the boys. Visual acuity was correlated with refractive error. It was found that myopia of even slight degree gave rise to visual defect, though the latter may not be sufficient to ensure that under the present school standards all cases would be detected and treated. Hypermetropia of considerable extent may be present without visual defect. The younger the child the more marked is the visual defect. Slight degrees of astigmatism often give rise to visual defect, though usually not greater than is indicated by 6/9, so that many low degrees of defect escape treatment. A suggestion is made that the borderline cases may be detected with advantage by placing a lens of +1 D. sphere before the eyes of children with barely 6/6 vision. In emmetropes, myopes of low degrees, and astigmatics this would cause a considerable lowering of visual acuity, so that they would be distinguished from the hypermetropes, who would pass with ease. The committee judges that the results obtained by this preliminary investigation are sufficiently promising to warrant the continuance of such work in the hands of one investigator, whereby a desirable uniformity of returns would be obtained.

FOOT-AND-MOUTH DISEASE

The Foot-and-Mouth Disease Committee of the Ministry of Agriculture and Fisheries has issued its fourth Progress Report,[1] covering the work initiated by the committee, as well as that performed in other countries, during the past three years. Advance has been steady, although slow—the slowness may in part be due to the inherent complexity and difficulty of the subject, and in part to the numerous changes in the research personnel; no fewer than fourteen workers have resigned after an average term of service with the committee of under eighteen months. Since the publication of the last report in 1928, perhaps the most important discovery has been the cultivation of the virus by Professor H. B. and Dr. M. C. Maitland, in flasks containing living tissue of embryo guinea-pigs. Somewhat similar results have independently been obtained by Heck on the island of Riems, and it seems certain that actual growth and multiplication has taken place. Curiously, the addition of serum to broth cuts short the life of the virus, while sterile skin and other tissues increase the time of survival. It has been shown also that virus in small pieces of skin immersed in liquids of an alkalinity approaching that of blood were still active after 71 to 105 days at 29° F. In blood dried on metal, brick, glass, or wood at 59° to 68°, virus only survived two to three days, although on hide, leather, or rubber its life was prolonged to 80 to 102 days. On wrapping materials at normal and at chilled-meat temperatures, it could live 45 days. In milk the virus is soon killed on souring, but, added to sterilized milk, it can live for at least 47 days at 39° and 30 days at 64.4°. In milk rapidly dried by spraying, it can live for some time longer than when dried by hot rollers. The best disinfectants are those which raise the alkalinity of the liquid used, and a 4 per cent. solution of washing soda is very effective for ordinary washing purposes. Hides can be disinfected by immersion for five hours in sodium bisulphate (1 in 10,000) or for two hours in sodium bifluoride (1 in 20,000) without damage to the skin. Experiments with cold storage suggest that if animals are killed at a highly infective stage of the disease, dressed, and chilled or frozen, they may remain infective for some weeks. At least three types of virus are known—O, A, and C; these produce disease and epizootics which are nearly or quite indistinguishable clinically, though an attack due to one type does not protect animals against the others; in cattle and pigs, however, there seems to be some overlapping or extension of the resistance produced by one of the types to infection with the others. The type most frequently found in Britain is the O type. The main sources of infection are cattle, pigs, and sheep, though other ruminants may easily be infected also. Man has been conclusively proved to be a possible host. Wild rats have been infected from guinea-pigs; and rabbits, hedgehogs, cats, and dogs can harbour the virus. Four different methods have been employed to produce specific immunity against the disease. Inoculation with large doses of serum from previously immunized cattle gives a considerable measure of protection for [illegible] and is effective for cattle exposed to infection in [illegible] and market. The serum should, of course, be [illegible]

[1] Ministry of Agriculture and Fisheries. Fourth Progress Report of the Foot-and-Mouth Disease Research Committee. London: H.M. Stationery Office. 1931. (7s. 6d. net.)

valent. Simultaneous inoculation with virus and serum diminishes the severity of the attack. This method has been used in Germany. Inoculation with attenuated virus has not yet been effective. Inoculation with formolized virus was introduced in 1926, and regularly produces a considerable degree of resistance, but it is necessary to use a virus of high potency and to inject a large amount. The immunity produced is probably of the same kind as that following an actual attack, but of a lower grade. This method has so far mostly been used experimentally with guinea-pigs because of the difficulty of obtaining sufficient quantities for larger animals. This is the method which gives the greatest promise of ultimately controlling the disease.

THE B.C.G. TRIAL AT LÜBECK

There is no sign that this trial is near its end. The reports in the German daily press do not make it clear whether the vaccine was given solely by the mouth or not. Advocates speak of "inoculation," but the technical witnesses mostly use words indicating oral administration, and this seems decisive. It is clearly stated that Dr. Altstaedt, after many of the deaths had occurred, gave to his own newborn infant—in order to demonstrate his faith—the vaccine with sugar and water, and that the infant swallowed it with gusto. An attempt to pre-judge the whole issue by speaking of the material used in Lübeck as something essentially different—"Deycke-vaccine"—was prevented by the judge's ruling that the material must be called "Calmette vaccine" or simply "the vaccine." The judge noted that the League of Nations Commission and the committee of the Académie de Médecine in Paris were convinced of the harmlessness of B.C.G. It was stated that Bulgarian doctors were prepared to give evidence of the Bulgarian tragedy, and that lists of the victims could be produced in court. Apparently an official denial was forthcoming from Bulgaria, and Professor Calmette had no knowledge of the occurrence. It was further stated that three doctors from Budapest were prepared to testify that three of twelve children who had died after the use of B.C.G. in Hungary owed their death to the vaccine. The court decided to call none of these doctors before it, nor Professor Calmette. A demonstration of methods was given at the laboratories, and the court studied the possibility of interchange of cultures. At one stage Dr. Hamel of the Reichsgesundheitsamt testified that the official attitude was, and had been throughout, to discourage or even prohibit the general use of B.C.G. in Germany. The October number of the *Annales* of the Pasteur Institute contains three articles of interest. Dr. Buschmann of Limburg concluded from his researches that B.C.G. is harmless to children, that from it virulent cultures cannot be obtained, and that the use of B.C.G. notably reduces mortality and morbidity. Professor Bang of Copenhagen vaccinated thirteen calves with B.C.G., and, later, gave virulent tubercle bacilli intravenously; the calves surviving were slaughtered about ten months later. One died of a severe infection within two months of the test injection, one was killed owing to advanced tuberculosis, and two when slaughtered had severe lesions; nine were healthy, but in three, "insignificant" lesions were present. Of the nine unprotected control calves which received the same infecting dose four succumbed in six weeks; two when slaughtered showed advanced infection; and three appeared healthy, but yielded lesions at necropsy. Dr. Jundell of Stockholm found that B.C.G. protected calves "to a certain extent" against subsequent artificial infection, but did not protect pigs.

ST. GEORGE'S FORTY YEARS AGO

In a pamphlet reprinted from the *St. George's Hospital Gazette* of June last, Sir Humphry Rolleston writes pleasantly of the hospital and its staff as he has known it in the forty years since he was appointed Curator of the Museum in 1890. The post of curator in those days was not often sought after for its own sake, for, as Frederic Hewitt (afterwards Sir Frederic) wrote of its duties:

> "I've calculi sorted
> And tumours imported,
> I've livers and kidneys and bladders and spleens,
> I stop here all day, and I mayn't go away
> Till I've done my own work and the most of the Dean's."

In Sir Humphry Rolleston's case it happily led to the medical staff and the honours which he bears so gracefully. Of the physicians and surgeons of 1890 none of the former, and only three of the latter, survive. Sir Humphry writes kindly of them all, but naturally with fullest knowledge of the physicians, although a specialist comes in for one of his fullest notices. This was Brudenell Carter, who lived to be 90, and whose undying enmity to Ernest Hart led him to describe this journal in a speech at a dinner of the Apothecaries' Society as "weakly." Carter himself was long connected with the *Lancet*, and for many years was a leader-writer on the staff of the *Times*. None of the six physicians and assistant physicians of 1890 has made much mark on medical history. W. Howship Dickinson probably had the greatest contemporary repute. He was a man of strong personality and a sarcastic wit; but, as Sir Humphry Rolleston says, his name is identified with "lost causes" in pathology. Nevertheless, Sir Thomas Barlow said of him: "This was the noblest Roman of them all." Such character sketches as these by Sir Humphry Rolleston are agreeable reading for those who knew the subjects of them, but of still more serious value to the medical historian of the future. It is greatly to be wished that more of our senior colleagues would put on record their recollections of the staffs of other hospitals. Parr's *Lives of the Fellows of the Royal College of Surgeons* has set a good example in this kind of work.

The next session of the General Medical Council will open on Tuesday, November 24th, at 2 p.m., when the President, Sir Donald MacAlister, B.., will take the chair and give an address. The Council will continue to sit from day to day until the termination of its business.

Professor Otto Warburg of the Kaiser Wilhelm Institut für Biologie, Berlin, has been awarded the Nobel 1931 prize for medicine for his researches on enzymes.

We regret to announce the death of Dr. James Sholto Cameron Douglas, professor of pathology in the University of Sheffield, and dean of the Medical School.

VITAMIN STANDARDS AND UNITS

RECOMMENDATIONS OF THE LONDON CONFERENCE

In June, 1931 (as already noted in these columns), a conference, composed of scientific investigators interested in vitamin research, was held in London under the auspices of the Permanent Standards Commission of the Health Organization of the League of Nations.[1] The conference, whose members were drawn from several European countries and the United States, met "to consider the possibility of accepting, by international agreement, a stable standard for each known vitamin, and of defining, in each case, in terms of such a standard, an arbitrary unit of activity for the corresponding vitamin; also, to consider whether, in each case, any method, or methods, for testing in comparison with the standard can be recommended by international approval." Before the conference met it had been agreed that in the present state of knowledge the question of standards and units could profitably be discussed only in the case of the following vitamins:

1. Fat-soluble vitamin A.
2. The antirachitic vitamin D.
3. The antineuritic vitamin B (also known as vitamin B_1).
4. The antiscorbutic vitamin C.

The problems with which the conference had to deal were of considerable practical and scientific importance. On the commercial side the desirability of being able to state exactly, in terms of units, the potency of different vitamin preparations is obvious, and before the conference met some steps in this direction had already been taken in several countries. For example, the last edition of the *United States Pharmacopoeia* defined a unit of vitamin A activity based on a rat-growth test. In recent years a solution of irradiated ergosterol, in terms of which a unit of vitamin D was defined, has been kept at the National Institute of Medical Research, Hampstead, and used by many commercial firms in standardizing their preparations. In Germany, firms dealing in preparations of irradiated ergosterol have found it necessary to establish a vitamin D unit on their own initiative. As regards foodstuffs, the rough-and-ready methods hitherto adopted of appraising vitamin content obviously need improvement. To read that a foodstuff contains "vitamin B_1 ++" and "vitamin A+" does not convey a very clear idea; the statement that it possesses roughly half the vitamin B_1 potency of yeast and one-tenth the vitamin A content of cod-liver oil provides more information, but still remains vague, because yeast and cod-liver oil are variable substances. Anyone who has attempted to tabulate the vitamin content of common foodstuffs from the experimental data now available will know that a considerable amount of pure guesswork is necessary, which the establishment of vitamin units should eventually eliminate. Similarly, in researches into the chemistry of the vitamins the adoption of vitamin units and standards common to investigators in all countries is of obvious importance. If, for example, an investigator wished to follow one of the vitamins through a series of fractionations, he would find it useful to have a standard of reference for use in estimating exactly the loss of potency at each stage, and the expression of his results in generally accepted units would greatly add to the value of the work.

Definition of Units

At the outset the conference found it necessary to decide on a question of principle—whether to define its units in terms of a biological test or in terms of a standard substance. It agreed unanimously in favour of the latter course, which has been followed in the standardization of other physiologically active substances, as, for example, insulin, immune serums, digitalis, etc. In the case of the vitamins, there is perhaps something to be said in favour of defining units in terms of the reaction of an animal. In large laboratories the rat, the animal most frequently used in vitamin experiments, can be "standardized" to some extent, and if all factors, particularly the breeding diet, are kept constant, the animals will not vary much from generation to generation in their reaction to a given amount of a particular vitamin. A conference held recently in New York in connexion with the Committee of Revision of the *United States Pharmacopoeia* recommended the adoption of units for vitamins A and D based on biological tests, which involved defining the breeding and experimental diets to be used. Such a method of establishing vitamin units may, however, lead to difficulties. Small laboratories do not possess the necessary supply of uniformly reacting test animals, and variations in the breeding and experimental diets, due to the different origins of the foodstuffs composing them, may be expected to occur. Other factors, besides diet, difficult to standardize, might make the reaction of a rat in one laboratory to a given amount of vitamin preparation different from that of a rat of the same age and weight in another. With material standards for comparison these possibilities of confusion are avoided.

The conference, in choosing suitable standards, had to consider a number of points, of which the most important was the question of stability. It is obviously necessary to guard carefully against the possibility of unnoticed deterioration in the standard substance. Other matters requiring consideration were the method of preparation of the standard, the conditions under which it should be kept, and the method of distribution.

Vitamin D

In the case of vitamin D, the preparation of irradiated ergosterol which has already been issued from the National Institute of Medical Research, Hampstead, was chosen as the international standard. This preparation has been in use for more than a year as vitamin D standard in Great Britain, and appears to possess the necessary qualifications. At room temperature it lose[s] potency, but it has been found to remain stable for [...] years when preserved at 0° C., in the absence [...] The method of preparing the standard soluti[on] defined, and it was agreed that when renewal [...] necessary a number of laboratories in different [...] should co-operate in comparing the new stand[ard] tion with the old, and thus ensure their equival[ence]. unit of vitamin D was defined as "the vitamin [...] of 1 mg. of the international standard soluti[on] ated-ergosterol." If, as is not unlikely, vit[amin D] is isolated in pure crystalline form during [the] years, the international unit can be redef[ined] of the pure substance.

Vitamin A

As standards of reference for vitamin A [...] suggested themselves—cod-liver oil and c[arotene]. fact that cod-liver oil, particularly when fr[esh] undergoes a loss of vitamin A potency due t[o] impairs its suitability as a standard. After a [...] however, further change is slow. Pure carotene is transformed into vitamin A in the liver. [...] the physiological effects of vitamin A when g[iven] small doses: 3 to 5γ will restore growth and c[ure] thalmia in vitamin A deficient rats (γ = 0.0[01] With regard to the stability of carotene, in r[elation] vitamin A activity, little is at present k[nown] fact that it consists of two isomers, α and β-c[arotene] of less importance, because these have l[ittle] possess almost similar biological activity.

ıe conference recommended the adoption of carotene ›orarily as an international standard of reference ·itamin A, with a selected sample of cod-liver oil second provisional standard. The choice of carotene :mphasized as provisional, and further investigation ; stability will be necessary before its permanent ility is assured. The preparation of carotene for s an international standard is to be made from a er of samples of pure carotene prepared in certain ed laboratories by Willstätter's[2] method, and the ational unit recommended is the vitamin A potency = 0.001 mg.) of the resulting mixture.

Vitamin B

nternational standard for the antineuritic vitamin conference recommended the absorption product *.min B prepared in the Medical Laboratory, Java,* · method of Seidell,[3] as described by Jansen and ı.[4] This preparation, which is extremely potent antineuritic vitamin, is made by extracting rice ıgs by dilute sulphuric acid, after which the is treated by fuller's earth. The earth, with the ı adsorbed upon it, forms the standard substance. as present knowledge goes loss of antineuritic ı does not occur even when the dry preparation is room temperature for some years ; moisture must r, be avoided, or bacterial decomposition will take The material has the disadvantage of being a ; substance, and probably contains other B s. The unit recommended was the antineuritic f *10 mg. of this adsorption product.*

Vitamin C

able standard of reference for vitamin C appears ready made. A number of observers have found : *juice of oranges and lemons varies very little* ıin C potency from year to year. The unit of C recommended was the vitamin C activity of . of fresh juice of the lemon *Citrus limonum.*

Methods of Biological Assay

nference did not discuss at any length the relative : different methods of biological assay. When : in units of a test substance is to be estimated, substance and the standard preparation are in- d simultaneously by the same method, and the stance should therefore show the same value in the standard, whatever biological technique is l. Practical confirmation of this was recently in the results of investigations planned and sub- o this conference by the Accessory Food Factors ee. For vitamin D tests, for example, the con- lecided that " the ' line ' test, *x*-ray examination, mination of the bone ash, are all equally reliable ," *but some recommendations* were made with o the minimum number of rats to be used for a ıation of antirachitic potency. In tests for B, the conference was satisfied that methods prophylactic and curative in type and employing ıe rat or pigeon as experimental animal may yield valid results."

standard preparations for vitamins A, B_1, and D be kept at the National Institute of Medical ch, Hampstead, which will act for this purpose on of the League of Nations Health Organization. thence they will be issued to suitable individuals nstitutions, under conditions defined by the .nce.

Commentary

While the recommendations of the conference are mainly visional, and may require revision in a few years, a ful advance has been made. The introduction of research. It is to be hoped that the units established will be widely used in assaying the vitamin content of medicinal preparations and foodstuffs. The task of re-investigating common foodstuffs, in order to estimate the number of vitamin units they contain, is not as formidable as it sounds. When this has been done, it should be possible to calculate not only the protein, fat, and carbohydrate content of human dietaries, but also their vitamin content. Certainly it should not be difficult to investigate in this manner the unbalanced diets which lead to deficiency disease. Sufficient knowledge of the vitamin value of different human dietaries should eventually enable us to estimate man's actual requirements in this respect.

WORK AND FINANCE OF VOLUNTARY HOSPITALS IN LONDON

The annual statistical review for 1930, just published by King Edward's Hospital Fund for London,[1] contains no evidence of any falling off, in the five-year period of the review, in the total amount of voluntary gifts to the maintenance of the hospitals of London. On the contrary, they increased during the three years 1928–30 from £1,689,000 to £1,836,000. Though an examination of the figures shows, as was to be expected from the financial stringency, some decrease in 1930 from the high figures of 1928 and 1929 in the amount received from the general body of subscribers and donors, this decrease was more than set off by the receipt of a large single donation of £100,000. If receipts for building and endowment are included, the total voluntary gifts in 1930 amounted to £2,942,000.

The total income of the 140 London hospitals dealt with in the review was £3,768,000, the highest figure recorded, and an increase of £157,000 on the previous year. Notwithstanding an advance of £131,000 in the total running expenditure, due to progress in various directions, including the upkeep of 350 additional beds, the aggregate surplus of income over expenditure for the year 1930 was £80,000. In 1929 it was £54,000. The financial results as a whole in 1930 were therefore better than in 1929.

If the individual hospitals are taken separately, there were 71 with surpluses and 69 with deficits ; in this respect 1930 was not so favourable as 1929, when 80 of these hospitals had surpluses ; but, taken as a whole, while the deficits came to £84,000 more than in 1929, the surpluses totalled £110,000 more. Some of the hospitals with a deficit were in a position of real difficulty, but hospitals with a deficit one year are often among those with surpluses in the next, as the result either of better fortune or of special efforts.

The question what effect the prevailing depression may have upon the finances of the London voluntary hospitals during 1931 cannot as yet be answered ; but whatever doubts are felt are no more than a recurrence of similar doubts felt a year ago regarding the results of 1930. The soundness of the position in London at the beginning of the year is demonstrated by the figures given in the King's Fund review for 1930, and is thus described in its concluding summary :

" The work of the voluntary hospitals in London continues to extend. The figures of the five years covered by this

[1] Statistical Review of the Work and Finance of the London (1s.)

review carry on from the preceding years the story of increased work. The number of in-patients treated daily in the London hospitals has increased by 16 per cent. in the last five years, while the out-patients have increased by over 6 per cent., and the total out-patient attendances by 20 per cent. This increased work is the outcome of the change that has gradually been taking place in the part played by the voluntary hospitals. These hospitals are no longer only a refuge for the indigent sick; the rise of an informed public opinion on the importance of the health of the individual for the social well-being, and the progress made in curative medicine and surgery, have not only increased the number of those patients that can be effectively treated, but have also led to demands from other classes of the community, and the hospitals have opened their doors to serve the common good.

"In the aggregate the receipts have kept pace with the increased maintenance expenditure. Except in 1926, current maintenance has been covered by income. To this result subscriptions and donations have contributed their share, this source of income showing a large increase in recent years, quite apart from the exceptional single donation of £100,000 in 1930, and this although heavy demands have been made by the hospitals upon the public for large schemes of rebuilding and of extension at existing hospitals and for buildings for new hospitals. In each of the last four years the annual receipts by the hospitals from voluntary sources for all purposes have exceeded two and a half million pounds, the highest figure being reached in 1930, when over £2,900,000 was received. The same tale of increased receipts is told by the figures for patients' payments, which have reached a higher total in each successive year. All this is proof that during recent years public interest in the voluntary hospitals has continued to grow, and that the basis upon which the voluntary hospitals rest has been steadily broadening.

"These facts show that the vitality of the voluntary system is unimpaired, and has proved adequate to discharge the heavier tasks imposed upon it by changing social conditions. The financial and vital statistics contained in this review demonstrate that, so far as London is concerned, the community is ready to support in ever-increasing measure what has been described as 'our unique heritage,' and that the voluntary hospitals have been strengthening their hold upon the confidence of the public."

COLONIES FOR MENTAL DEFECTIVES

REPORT OF DEPARTMENTAL COMMITTEE

In January, 1930, the Board of Control, with the approval of the Minister of Health, appointed a committee with the following terms of reference.

"To consider and report what are the essential structural requirements of a complete colony for mental defectives of all types, and to what extent the cost could be reduced by the adoption of semi-permanent or temporary buildings or other new methods of construction, having regard to the comparative cost of maintenance as well as the initial capital expenditure involved."

The committee's report has now been published.[1] Although not required to deal with questions of policy, the committee states that its inquiries inevitably involved some consideration of the present-day method of housing defectives in "colonies," as compared with the older method of placing them in large barrack-like structures, and that the evidence received was strongly in favour of the colony principle.

"A complete colony should contain all the structures necessary for the housing, training, occupation, and recreation of defectives of all grades and ages, and the arrangements should be designed with reference to the fact that the great majority of the colonists will reside there for many years, and some for the duration of life."

The main purpose of the committee was to explore the possibilities of effecting economies in construction, and after an exhaustive inquiry it now sets out the essential requirements. While it has not been able to suggest major economies on present practice, a number of suggestions are made for effecting economies which, when taken together over a complete scheme, may be expected to be appreciable. To some extent the committee's suggestions would modify the standards now aimed at, but the comfort and general amenities, and the space allowed per patient, would not be affected. While preserving the colony idea of detached units grouped round a common administrative centre, the committee recommends closer concentration of the buildings and departure from the separate villa principle to the extent of building certain of the homes in semi-detached pairs. This recommendation alone would result in an estimated saving of £300 on each villa.

SIZE OF COLONIES

The question of the size of a colony is one which affects greatly the question of cost. Considerations of efficient classification, the need for a resident medical administrator, and the provision of essential facilities for occupations, recreation, and medical treatment, lead the committee to the view that no colony should be erected for fewer than 520 beds. But considerations of economy indicate that the administrative units essential to success should be made to serve not less than 880 beds, and the committee recommends that future colonies should be constructed ultimately to contain at least this number. Larger numbers would make for still further economy and efficiency, and the only practical limit of size would be imposed by the size of the geographical area to be served by the colony. This must not be so large that reasonably frequent visits by relatives and friends would be unduly difficult or expensive. The majority of local authorities would not, for themselves alone, need a colony of economic size, and the committee urges that they should be persuaded to combine in the provision of joint colonies.

METHODS OF CONSTRUCTION

On the question of permanent *versus* semi-permanent or other methods of construction, the committee, after careful inquiry, reaches the conclusion that "if the permanent construction is treated with due regard to lightness and simplicity, very little initial, and probably no ultimate, saving is likely to be effected by adopting semi-permanent or temporary constructional methods," except in the case of workshops, farm buildings, and similar structures. This conclusion is based mainly on the operation of loan charges for the different types of construction; but there are other than economic factors, and it suggests that local authorities would themselves be the best judges of what was best in any particular case.

Apart from its suggestions for effecting economies in the cost, necessarily heavy, of building colonies for mental defectives, the report of the committee should be of value to local authorities, because it defines a minimum standard of accommodation, while yet preserving decent conditions of residence for this afflicted section of the community. A series of sketch plans, illustrating the committee's suggestions for planning different kinds of homes, appears as an appendix.

ATTITUDE OF THE BOARD OF CONTROL

In a circular enclosing copies of this report the Board of Control says that in the existing financial situation they do not desire to urge local authorities who have not yet provided mental deficiency colonies to embark upon schemes of this kind at present. But it anticipates that many authorities will have under consideration proposals for such schemes with a view to their inception when circumstances permit. Bearing in mind the need for reasonable economies in the provision of colonies, the Board accepts generally the recommendations of the committee, and it will be prepared to approve proposals on these lines as and when such schemes proceed. At the same time, the Board's general acceptance of the recommendations will not preclude it from approving proposals which may depart from the recommendations (for example, with respect to air space and the arrangement of beds in dormitories), but can be justified on their merits in particular cases.

THE GENERAL ELECTION

MEDICAL MEMBERS OF THE NEW PARLIAMENT

The following nine medical men who were members of the last Parliament have been re-elected to the House of Commons at the recent General Election: Dr. Walter E Elliot, Dr. F. E. Fremantle, Sir Ernest Graham-Little, Dr. H. C. Haslam, Dr. Joseph Hunter, Dr. J. H. Morris-Jones (unopposed), Dr. Alfred Salter, Professor Thomas Sinclair (unopposed), and Dr. J. H. Williams.

The following seven medical men have also been elected, one of whom, Sir Henry Jackson, sat as *member for the* same constituency in the House of Commons from 1924 to 1929: Dr. J. D. Cooke, Dr. G. B. Hillman, Dr. A B. *Howitt, Sir Henry Jackson, Dr. J. W. Leech, Dr. W. J.* O'Donovan, and Dr. J. V. Worthington.

SUCCESSFUL CANDIDATES: POLLING FIGURES

The following are the polling figures at all the contested elections in which medical candidates were successful. An asterisk denotes that a candidate sat in the last Parliament.

HAMMERSMITH (SOUTH):	
Dr J. D Cooke (C)	21,018
*D. Chater (Lab)	8,390
GLASGOW (KELVINGROVE):	
*Dr. W E Elliot (C)	21,481
J Winning (Lab)	12,415
HERTFORD (ST ALBANS):	
*Dr. F E Fremantle (C)	36,660
Miss M Whateley (Lab)	10,289
LINCOLNSHIRE (HORNCASTLE):	
*Dr. H C. Haslam (C)	18,100
G. H. Dutton (L)	8,788
WAKEFIELD:	
Dr G. B *Hillman (C)*	15,831
*G H. Sherwood (Lab)	11,774

Major A G. Church (Nat Lab)	3,134

MEDICAL CANDIDATES NOT ELECTED

The following members of the medical profession were defeated at the polls Several had previously represented or contested either the same or other constituencies An asterisk denotes that a candidate sat in the last Parliament

Dr F G Bushell (Lab), Somerset (Taunton)
Dr C R Cooke Taylor (L Nat), Camberwell (Dulwich)
*The Right Hon Christopher Addison (Lab), Willesden (South East)
Dr Esther Richards (Lab), Pudsey (West)
*Mr Somerville Hastings (Lab), Reading
Dr W S Rowell Thomas (L), Ilford
*Dr L Haden Guest (Lab), Bucklemshire (Wycombe).
Dr R A Lester (Lab) Hampshire (Winchester)
*Dr T Drummond Shiels (Lab) Edinburgh East
*Dr R Forgan (New Party), Renfrew (Western)

England and Wales

Centenary of the York Medical Society

The centenary of the York Medical Society was celebrated on October 28th. The president (Mr J. S Hughes), in welcoming the large audience, which included delegates from other medical societies, described the conditions prevailing a hundred years ago, when science seemed to be bride-bound, and medicine and surgery were a mass of empiricism and mediaevalism. One of the founders of the British Association at York at that time was a member of the medical profession, Dr. Wade; he subsequently brought into being, in 1831, the York Medical Society, for the advancement of medicine and surgery. The society had had a continuous existence, and had rendered distinguished service to medical science Lord Moynihan, P.R C S, delivered an address on ancient medicine and surgery, commenting particularly on the occurrence of osteo-arthritis in prehistoric Egypt, and on the operation of trephining in Peru, presumably to relieve "possession by evil spirits" With the aid of a lantern slide he showed how a fractured forearm had been united by expert hands in 1250 B.C. Dr. Watts Eden, President of the Royal Society of Medicine, who proposed a vote of thanks to Lord Moynihan, condemned the over-specialization which was too current, and emphasized the value of such organizations as the York Medical Society in affording the means of bringing specialists and general practitioners together, to the great advantage of both. The centenary banquet was attended by the Archbishop and the Dean of York, the Lord Mayor, and representatives of medical practitioners from all parts of the county. The Archbishop, responding to the toast of "The Clergy," proposed by Mr. E. R. Dodsworth, pleaded for closer association between the medical profession and the Church. There was always, he said, a great danger of drifting into some remoteness or unreality when any interest was pursued in isolation, and particularly when it had a scientific aspect. Human bodies themselves could not be treated as though the physical and mental sides were independent, for the personality was a unity, and so a close harmonious co-operation of those engaged in healing was much to be desired. Sir Squire Sprigge, proposing the health of Lord Moynihan, commented on the pioneer work in surgery for which his fame was world-wide Lord Moynihan, in his reply, said that an objective of his life had been to bring surgeons together, and to make the world of English surgeons count for more than it had ever previously done The formation of the Association of Surgeons of Great Britain and Ireland was gradually rendering it impossible for second-rate work to go on in any clime, and surgeons were being united in personal friendship as well as by professional interests in a way

which would have been impossible twenty years ago. As disciples of Lister they had made British surgery the safest and best in the world, and surgery was surely the greatest of the arts. The toast of "The Guests" was proposed by Dr. H. Yellowlees of London, formerly medical superintendent of the York Retreat; Professor D. P. D. Wilkie of Edinburgh, and Dr. W. G. Willoughby, President of the British Medical Association, responded.

Chadwick Lecture on Cancer

A Chadwick Public Lecture, entitled "The prevention of cancer," was given in the Great Hall of the British Medical Association House, Tavistock Square, by Dr. F. J. McCann, on October 30th, with Sir William Collins in the chair. Dr. McCann's first point was that the proper study of human cancer was the cancer patient, and any attempt to relegate the clinician to the background in favour of the laboratory worker should be discouraged. Both were capable of rendering service in their own sphere, but that of the clinician was the larger. After discussing briefly the age incidence and distribution of cancer he declared that this was largely a preventable disease. It did not appear like a bolt from the blue, but was usually preceded by a period of subnormal health varying in intensity and duration. It was not a local but a systemic disease, and unless the local removal or destruction of the growth was aided by general treatment the proportion of cures would not increase. The cancer patient should remain under observation for the rest of his life. Strict bodily cleanliness occupied a foremost place among the methods of preventing cancer, and its utility was not only exemplified in dealing with "occupational cancer," but also in all situations where chronic irritation was allowed to persist. Chronic irritation stood out as the most common single exciting cause of surface cancer, and full advantage had not been taken of this knowledge. Long-continued irritation insufficient to cause rapid local destruction of tissue was the most potent. The irritant might be mechanical, chemical, bacterial, actinic, or from animal parasites. Prevention or removal of chronic irritants was the most hopeful method of hindering the appearance of a cancerous growth. The lecturer then indicated how this principle could be applied to cancer, not only on the surface of the body, but also in the internal organs. Further, the value of the study of pre-cancerous states was stressed as well as the great importance of early recognition of cancer. A striking example was furnished by cancer of the uterus, which had dropped from the top of the list to fifth place. In 1907 the lecturer acted as chairman of a committee of the British Medical Association formed to encourage the earlier recognition of cancer of the womb, and leaflets giving the early signs and symptoms were distributed to nurses and midwives, and a synopsis published in the leading medical journals. This action had been instrumental in directing increased attention to early recognition, and in consequence the results of treatment had been improved. What had been achieved for uterine cancer could be achieved for other organs of the body. The general problem was to prevent senility of the tissues, whether premature or excessive. The necessity for pure air and sunlight was as great in the prevention of cancer as in that of tuberculosis, while open-air treatment should be the rule after operations for cancer. Removal of the local disease or its destruction formed only a part of the treatment of cancer; removal of "focal sepsis" was an important means of tissue betterment. A well-balanced diet, suitable to age, sex, occupation, habits, and environment, was requisite. The effect of toxic poisoning from the intestine, and the influence of syphilis and chronic alcoholism in relation to tissue degeneration, were pointed out, as well as the reasons for disregarding the microbic theory of cancer. In Dr. McCann's view the cause of cancer was probably some chemical product of tissue degeneration, varying in quantity in different bloods and at different times in the same blood, and capable of exciting irregular and uncontrolled growth of epithelial cells in localities naturally predisposed or rendered suitable by chronic irritation, inflammation, disease, or degeneration, and these cells in turn producing a similar substance, augmenting that which existed in the circulating blood. The problem of cancer was the problem of cell growth. Certain of the internal secretions had the power of exciting and others of restraining cell growth, and it was in this direction that the best means of providing a genuine cure for cancer must be looked for. But prevention was better still, and early recognition essential

Expected Measles Epidemic in London

An epidemic of measles in London, according to a report of the Central Public Health Committee of the London County Council, is expected during this autumn and winter. Measles epidemics in London appear to occur biennially, beginning in the late autumn, reaching their meridian in March, and taking some six or seven months to complete the circle of London. The last epidemic occurred in the autumn and winter of 1929-30, and the next is therefore almost due. During each measles epidemic in London not fewer than 50,000 children are affected. The committee points out that measles is an infection which does not lend itself ideally to hospital treatment, and therefore home nursing should be encouraged in all cases where it can be carried out under reasonably favourable conditions. Where satisfactory home nursing cannot be obtained, every effort should be made to secure the patient's admission to hospital at as early a stage of the illness as possible. The Council has 4,634 beds in its town fever hospitals, and 2,868 more in outlying and convalescent hospitals. During measles epidemics every case of scarlet fever that can either be kept at home or sent to one of the outlying hospitals renders a hospital bed available for measles. It is considered that if measles cases are admitted before complications have developed, a period of fourteen days is usually adequate for hospital treatment. The number of beds that can be set apart for measles depends largely on the incidence of diphtheria, which must be given priority of admission over both scarlet fever and measles. It much depends also upon the incidence of small-pox. If the fever hospital accommodation is unduly taxed for other conditions, arrangements will have to be made for assistance from the general hospitals under the Council's control during the period of expected greatest pressure—namely, February to April, 1932. Attention is drawn to the assistance which the public, especially parents, can give. Despite much propaganda, the belief persists that measles can be lightly treated without medical aid or nursing assistance; yet during the last four years measles has caused eight times as many deaths as scarlet fever and one and a half times as many as diphtheria. The deaths from measles in London are diminishing, however, as seen from the figures for recent quinquenniums:

1906–10	9,538	1921–25	3,855
1911–15	9,596	1926–30	3,715
1916–20	5,830		

Important points in mitigating the effects of an epidemic are: (1) to make every effort to postpone contracting the disease until after the third or fifth year, for the younger the child the greater is the risk of serious illness; (2) to secure adequate medical, nursing, and hospital care; (3) to have regard to the fact that measles is particularly fatal among children under five living under unfavourable conditions.

St. Luke's Day Service at Portsmouth

A special service was held at the Cathedral, Portsmouth, on St. Luke's Day, when there was a large congregation, including the Lord Mayor and Lady Mayoress, Sir Harold Pink, chairman of the Royal Portsmouth Hospital, Surgeon Captain J. S. Dudding, R.N., members of the Portsmouth Division of the British Medical Association, together with representatives of the Voluntary Aid Detachment of the British Red Cross Society and nurses from the local institutions. The special service was conducted by the Provost, and the lessons were read by Dr. David McAskie and Dr. F. C. B. Gittings, the chairman and secretary respectively of the Portsmouth Division. In the course of his sermon the Bishop of Portsmouth quoted the following statement of a young modern thinker: "The great sin which all scientists must avoid is that of despairing of the ultimate arrival at the unity of the universe." He remarked that if this objective was lost sight of the result would mean the collapse of research. If St. Luke, the beloved physician and the patron saint of the medical profession, returned to this earth and witnessed the works of modern medicine he would recall the words: "Ye shall do greater things than these." The life of a physician meant much intellectual and physical hardship, and only by splendid self-discipline and self-sacrifice could research be carried on with that great unity in view. Physics had taught that life was not an output of fundamental matter, so much as an interrelative series of events with a definitely forward movement, and they must regard themselves as adventurous climbers with an Everest to conquer. For the scientist, discovery sometimes meant rebuilding his house with what seemed to be broken tools. Anybody with a new truth to give the world was an object of derision and persecution, and often found his discovery a crown of thorns. Indeed, the crucifix was never far from the truth-teller, but comfort emanated from the fact that He who told the truth two thousand years ago was still in our company and essential to our lives.

Medical Superintendent of North-Eastern Hospital

Dr. F. H. Thomson, medical superintendent of the North-Eastern Hospital, South Tottenham, retired under the age limit in October. He entered the service of the Metropolitan Asylums Board in 1890, became medical superintendent in 1906, and in 1926 was appointed by the Board chief medical officer in the infectious diseases hospitals service. The London County Council states that "he has carried out his responsible duties with conspicuous ability and zeal, and has rendered important services in the administration of the infectious diseases hospitals." Twenty-five applications were received in response to public advertisement for appointment as medical superintendent in the Public Health Department, for duty in the first instance at the North-Eastern Hospital. Dr. E. H. R. Harries, medical superintendent of the City Fever Hospital, Birmingham, and clinical lecturer on fevers, Birmingham University, has been chosen.

Strangeways Research Laboratory

The report for 1930 of the trustees of the Strangeways Research Laboratory at Cambridge indicates that the work of this organization is proceeding satisfactorily, despite the lack of money which would enable extensions to be undertaken and the endowment fund to be increased. All available space is now being devoted to research; eleven workers are at present accommodated in the building, and one is temporarily working abroad. A comprehensive scheme for studying the effects of radiation upon normal and malignant cells has been devised in collaboration with various university departments and with Addenbrooke's Hospital. The radio-sensitivity of malignant cells is being investigated by means of the tissue culture technique, and, in this connexion, it may be recalled that the British Institute of Radiology presented its Roentgen award for 1930 to Dr. F. G. Spear, a member of the scientific staff of the laboratory, for his paper on the immediate and delayed effects of radium on tissue cultures *in vitro*. Experimental work in embryology and histology has been promoted, with special reference to bone formation and the repair of fractures. Various articles have been published by Dr. Honor Fell and other members of the staff of the laboratory, and communications have been made to learned societies.

Ireland

Allocation of Sweepstakes Money

A Bill was recently introduced in the Dail, and read a first time, to amend the Public Charitable Hospitals Act so that some of the money already provided by statute for allocation to county and district hospitals should be allocated to nursing institutions. A "nursing organization" is defined as one "which has for its sole object the nursing and providing of nurses for poor persons suffering from physical diseases or injuries, or women in childbirth." Section 2 provides that, notwithstanding anything contained in Section 6 of the Amending Act, one-twenty-fifth part of the portion of every available surplus paid to the Minister for Local Government and Public Health under that section shall be paid or applied by him in such manner as he shall think proper to or for the benefit of such nursing organizations as he shall think fit. It also provides that where the Minister under this section pays any money out of available surplus to a nursing organization, he may require as a condition that such money shall be applied only for or in relation to the promotion of the objects of the organization in particular areas specified by him.

Drain on Insurance Funds

At the annual meeting of the Association of Trade Union Approved Societies in Dublin, Mr. L. J. Duffy, who presided, stated that a number of societies which had provided additional benefits, such as dental treatment and hospital treatment, before July last, were now obliged, as a result of the third quinquennial valuation, to discontinue these services, and that the societies as a whole had not nearly so much money available for additional benefits during the present valuation period as in the previous period, because of increased expenditure on sickness and disablement benefit. The increase in sickness claims was confirmed by a subcommittee of the Health Insurance Advisory Committee, which had given much consideration to the problems arising out of excessive expenditure on benefits, but no improvement could be hoped for so long as the present volume of unemployment continued. Many thousands of workers were unemployed for long periods, and probably double as many were employed only intermittently. The experience of approved societies and of sickness insurance funds in the Irish Free State seems to be similar to that of other countries where considerable unemployment exists.

Blind People in the Irish Free State

Commenting on a leading article in the *Irish Times*, Dr. J. S. Quin draws attention to the needs of the blind in the Free State, and to the work that has recently been started by the National Council for the Welfare of the Blind in Ireland, of which he is honorary treasurer.

which would have been impossible twenty years ago. As disciples of Lister they had made British surgery the first and best in the world, and surgery was surely the greatest of the arts. The toast of "The Guests" was proposed by Dr. H. Yellowlees of London, formerly medical superintendent of the York Retreat; Professor D. P. D. Wilkie of Edinburgh, and Dr. W. G. Willcocks, President of the British Medical Association, responded.

Chadwick Lecture on Cancer

A Chadwick Public Lecture, entitled "The prevention of cancer," was given in the Great Hall of the British Medical Association House, Tavistock Square, by Dr. J. J. McCann, on October 30th, with Sir William Collins in the chair. Dr. McCann's first point was that the proper study of human cancer was the cancer patient, and any attempt to relegate the clinician to the background in favour of the laboratory worker should be discouraged. Both were capable of rendering service in their own sphere, but that of the clinician was the larger. After discussing briefly the age incidence and distribution of cancer he declared that this was largely a preventable disease. It did not appear like a bolt from the blue, but was usually preceded by a period of subnormal health variable in intensity and duration. It was not a local but a systemic disease, and unless the local removal or destruction of the growth was aided by general treatment the proportion of cures would not increase. The cancer patient should remain under observation for the rest of his life. Strict bodily cleanliness occupied a foremost place among the methods of preventing cancer, and its utility was not only exemplified in dealing with "occupational cancer," but also in all situations where chronic irritation was allowed to persist. Chronic irritation stood out as the most common single exciting cause of surface cancer, and full advantage had not been taken of this knowledge. Long-continued irritation insufficient to cause rapid local destruction of tissue was the most potent. The irritant might be mechanical, chemical, bacterial, actinic, or from animal parasites. Prevention or removal of chronic irritants was the most hopeful method of hindering the appearance of a cancerous growth. The lecturer then indicated how this principle could be applied to cancer, not only on the surface of the body, but also in the internal organs. Further, the value of the study of pre-cancerous states was stressed as well as the great importance of early recognition of cancer. A striking example was furnished by cancer of the uterus, which had dropped from the top of the list to fifth place. In 1907 the lecturer acted as chairman of a committee of the British Medical Association formed to encourage the early recognition of cancer of the womb, and leaflets giving the early signs and symptoms were distributed to nurses and midwives, and a synopsis published in the leading medical journals. This action had been instrumental in directing increased attention to early recognition, and in consequence the results of treatment had been improved. What had been achieved for uterine cancer could be achieved for other organs of the body. The general problem was to prevent senility of the tissues, whether premature or excessive. The necessity for pure air and sunlight was as great in the prevention of cancer as in that of tuberculosis, while open-air treatment should be the rule after operations for cancer. Removal of the local disease or its destruction formed only a part of the treatment of cancer; removal of "focal sepsis" was an important means of tissue betterment. A well-balanced diet, suitable to age, sex, occupation, habits, and environment, was requisite. The effect of toxic poisoning from the intestine, the influence of syphilis and chronic tissue degeneration, were pointed out, as well as the reasons for disregarding the microbic theory of cancer. In Dr. McCann's view the cause of cancer was probably some chemical product of tissue degeneration, varying in quantity in different bloods and at different times in the same blood, and capable of exciting irregular and uncontrolled growth of epithelial cells in localities naturally predisposed or rendered suitable by chronic irritation, inflammation, disease, or degeneration, and these cells in turn producing a similar substance, augmenting that which existed in the circulating blood. The problem of cancer was the problem of cell growth. Certain of the internal secretions had the power of exciting and others of restraining cell growth, and it was in this direction that the best means of providing a genuine cure for cancer must be looked for. But prevention was better still, and early recognition essential.

Expected Measles Epidemic in London

An epidemic of measles in London, according to a report of the Central Public Health Committee of the London County Council, is expected during this autumn and winter. Measles epidemics in London appear to occur biennially, beginning in the late autumn, reaching their meridian in March, and taking some six or seven months to complete the circle of London. The last epidemic occurred in the autumn and winter of 1929–30, and the next is therefore almost due. During each measles epidemic in London not fewer than 50,000 children are affected. The committee points out that measles is an infection which does not lend itself ideally to hospital treatment, and therefore home nursing should be encouraged in all cases where it can be carried out under reasonably favourable conditions. Where satisfactory home nursing cannot be obtained, every effort should be made to secure the patient's admission to hospital at as early a stage of the illness as possible. The Council has 4,634 beds in its town fever hospitals, and 2,868 more in outlying and convalescent hospitals. During measles epidemics every case of scarlet fever that can either be kept at home or sent to one of the outlying hospitals renders a hospital bed available for measles. It is considered that if measles cases are admitted before complications have developed, a period of fourteen days is usually adequate for hospital treatment. The number of beds that can be set apart for measles depends largely on the incidence of diphtheria, which must be given priority of admission over both scarlet fever and measles; much depends also upon the incidence of small-pox. If the fever hospital accommodation is unduly taxed for other conditions, arrangements will have to be made for assistance from the general hospitals under the Council's control during the period of expected greatest pressure—namely, February to April, 1932. Attention is drawn to the assistance which the public, especially parents, can give. Despite much propaganda, the belief persists that measles can be lightly treated without medical and nursing assistance; yet during the last four years measles has caused eight times as many deaths as scarlet fever, and one and a half times as many as diphtheria. The deaths from measles in London are diminishing, however, as seen from the figures for recent quinquenniums:

1906–10	9,538	1921–25	3,859
1911–15	9,596	1926–30	3,715
1916–20	5,830		

Important points in mitigating the effects of an epidemic are: (1) to make every effort to postpone contraction of the disease until after the third or fifth year, because the younger the child the greater is the risk of serious illness; (2) to secure adequate medical, nursing, and hygienic care; (3) to have regard to the fact that measles is particularly fatal among children under-nourished or living under unfavourable conditions.

St. Luke's Day Service at Portsmouth

A special service was held at the Cathedral, Portsmouth on St Luke's Day, when there was a large congregation including the Lord Mayor and Lady Mayoress Sir Harold Pink, chairman of the Royal Portsmouth Hospital, Surgeon Captain J S Dudding RN members of the Portsmouth Division of the British Medical Association, together with representatives of the Volunteer Aid Detachment of the British Red Cross Society and nurses from the local institutions The special service was conducted by the Provost, and the lessons were read by Dr David McKelvie and Dr I C B Gittins the chairman and secretary respectively of the Portsmouth Division In the course of his sermon the Bishop of Portsmouth quoted the following statement of a modern thinker "The great sin which all seem to shun must avoid is that of despairing of the ultimate arrival at the unity of the universe" He remarked that if this objective was lost sight of the result would mean the collapse of research If St Luke the beloved physician and the patron saint of the medical profession, returned to this earth and witnessed the works of modern medicine he would recall the words Ye shall do greater things than these" The life of a physician meant much intellectual and physical hardship and only by splendid self discipline and self sacrifice could research be carried on with that great unity in view Physics had taught that life was not an output of fundamental matter, so much as an interrelative series of events with a definitely forward movement, and they must regard themselves as adventurous climbers with an Everest to conquer For the scientist, discovery sometimes meant rebuilding his house with what seemed to be broken tools Anybody with a new truth to give the world was an object of derision and persecution, and often found his discovery a crown of thorns Indeed, the crucifix was never far from the truth teller, but comfort emanated from the fact that He who told the truth two thousand years ago was still in our company and essential to our lives

Blind People in the Irish Free State

Commenting on a leading article in the *Irish Times* Dr J S Quin draws attention to the needs of the blind in the Free State, and to the work that has recently been started by the National Council for the Welfare of the Blind in Ireland, of which he is honorary treasurer

This society, which is under the patronage of the Governor-General and Mrs. McNeill, is the direct result of the realization of this need by Miss Alice S. Armitage, daughter of the late Dr. Armitage, who founded what is now the National Institute for the Blind, and first introduced the Braille system into Great Britain. Membership is open to all interested on payment of an annual subscription of half a guinea, and the executive committee is elected annually by the general body of the members at the annual meeting. The aims and scope of the council are briefly as follows: to co-ordinate the work of the Richmond National Institution, St. Joseph's, Drumcondra, St. Mary's Merrion, Irish Association for the Blind, Irish National League of the Blind; to promote the formation of local county committees; to provide home teachers and visitors for the blind in their own homes; to print and circulate Braille magazines and books; and to facilitate the sale of work done by the blind, whether in institutions or in their own homes. The blind poor receive State pensions and allowances under the Blind Persons Act, but much more than financial help is required—for example, education in Braille and in handicrafts, the provision of facilities for higher education in suitable cases, and, above all, the realization that sympathetic assistance, rather than indiscriminate charity, helps the blind to retain their independence and to share in the normal life of the community. The council has already appointed a home teacher for the Dublin area, where, according to the Government registers, over 600 blind people are living in their own homes. The need for extending this side of the work is obvious.

Scotland

Edinburgh University

A graduation ceremony was held at Edinburgh University on October 24th for the conferment of degrees in arts, commerce, law, and science. Principal Sir Thomas Holland presided, and in the course of his address referred to the approaching celebration (in 1933) of the 350th anniversary of the foundation of the University. A volume, he said, was in preparation which would bring the history of the University up to date, thereby amplifying the volume published by Sir Alexander Grant in 1884, on the occasion of the tercentenary festival. He also referred to the desirability of establishing, in connexion with the anniversary, local associations and clubs of the 18,000 graduates who were on the General Register of the University. There were already in Great Britain about a dozen local associations and clubs of Edinburgh graduates, but it would be well if the meeting at Edinburgh in 1933 could exchange greetings with corresponding gatherings in various parts of the world. He hoped that copies of the new history of the University would be available for such meetings. In referring to the inauguration of two new chairs in child life and health and in psychology (*British Medical Journal*, October 24th, p. 772, and October 31st, p. 821), the principal remarked that Dr. G. M. Robertson, professor of psychiatry, had established a children's clinic at the Hospital for Nervous Diseases at Morningside. These three chairs laid the foundation for a systematic and correlated group of researches on the physical and mental aspects of children's problems, and the results obtained promised to be of special economic value to the country. Moreover, they offered the beginnings of a distinctively new school of investigation in Edinburgh in connexion with the work carried out with growing success in the department of social study.

Glasgow University

The half-yearly meeting of Glasgow University General Council was held on October 28th, Principal R. S. Rait presiding. A proposal was made that a University Club should be founded for the purpose of providing a common meeting place for alumni, so that contact might be maintained between former graduates of the University. It was intimated by Mr. C. A. Oakley that a prospective membership of 750 had been secured. The principal announced the receipt of a cordial letter from the retiring Lord Rector, Mr. Stanley Baldwin, in which he expressed the hope of having an opportunity of coming again to Glasgow University. Dr. John F. Fergus and Dr. David Baird Smith were reappointed representatives of the council on the University Court for a term of four years.

Compensation for Death in Hospital

The recent settlement of an action in connexion with the death of a patient in hospital presents points of interest to the medical profession. The action was brought by Mrs. J. Quaine or Reilly of Glasgow, against Alexander Donald McLean, male nurse, of Glasgow, for payment of £1,000 as damages for the death of her son, Richard Reilly, who was admitted to Stobhill Hospital, Glasgow, on September 12th, 1930, suffering from an epileptic fit. It was alleged that the defender, who was on duty in the ward, used unnecessary force for the purpose of keeping the patient in bed, and that in consequence the patient died two days later. The defender denied fault, and said that Reilly became very violent, attempted to strike the doctor and his mother, and fell out of bed. He explained that no restraint was used greater than was usual and proper for the patient's own security and care, and that he was not responsible for the injuries sustained. The case was finally settled out of court, the pursuer accepting £300 and expenses in settlement of the action.

Correspondence

A CHRISTMAS APPEAL

SIR,—For many years I have asked members of the medical profession to subscribe at this time of the year in order that the Royal Medical Benevolent Fund may distribute Christmas gifts. These gifts are made to poor widows and daughters of our professional colleagues, and also to medical men who are infirm or unable to work through illness, and whose savings are exhausted. I know the times are difficult for everyone, but I feel confident that those who can spare even a small donation will do so again this year so that even greater hardship should not fall on those least able to bear it.

It is the hope of the committee to distribute 30s. to each of the annuitants and the poorest of the grantees at Christmas. I am most anxious that none should look in vain this Christmas for the gift which can bring a few additional necessities of life and extra comforts to their homes. It is difficult for us to realize that "these homes" are often only a bed-sitting room of a very cheap rental.

May I ask your readers to forward their donations, however small they may be? Cheques, postal orders, or even stamps should be addressed to the honorary treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, W.1.—I am, etc.,

THOMAS BARLOW,
President.

London, Oct. 27th.

NEO-HIPPOCRATISM

SIR,—The defence of neo-Hippocratic methods of diagnosis and treatment made by Dr. Robert Hutchison from the important tribune of the Harveian Orator of the Royal College of Physicians—a defence on which you comment in your issue of October 24th—is, I think, of great significance for contemporary medical thought and practice in this country. As I have devoted to this subject long years of teaching and many publications, I should like to add a few words of comment.

In the return towards the methods of Hippocrates, which often occurs in the course of the history of medicine in periods of medical crisis, British physicians have always played an important part. When in the fifteenth and sixteenth centuries medicine had degenerated into a collection of narrow scholastic ideas and of superstitions, Thomas Linacre was among those who brought medicine into the right path by propagating the real conceptions and methods of Hippocrates and of the ancient Greek physicians. When in the seventeenth century medicine had been submerged by unbridled speculations and dogmas, Sydenham terminated that crisis by reintroducing the Hippocratic method of clinical observation. Nowadays, when medicine has come to a deadlock on account of the narrow mechanistical and organic principles of the nineteenth century, which have led to therapeutical nihilism, it is to the experimental demonstration of the integration of man made by the British physiologists, and to the clinical teaching of Sir James Mackenzie, that we owe for the greatest part the neo-Hippocratic movement that characterizes our post-war medicine.

Neo-Hippocratism is founded on the conception of the integration, of the "wholeness" of the human body. Man cannot be considered as a bundle of organs or a colony of cells, nor as constituted by a separate body and a separate soul, but as an integrated whole. Thus, diagnosis and treatment refer to the whole individual, and consideration of special groups of diseases can no longer be accepted. Specialties can develop only in surgery because surgical specialties refer to operative technique, but they cannot exist in internal medicine, because internal medicine has to consider the whole individual, and thus is "all or none." The real specialist in internal medicine is not the cardiologist, the gastro-enterologist, or the neurologist, who run after non-existent fictional or local diseases, but the internist, who sees and treats the patient as a whole.

The basis of neo-Hippocratic medicine is a special diagnostic procedure, the "diagnosis of the person," which is individual, complete, and dynamic. It is individual because its object is the understanding of the individual patient, and not the placing upon that patient of a fictional nosographical label. It is complete because it considers the whole individual and the individual as a whole, and not merely a local lesion or functional disturbance. It is dynamic because through it the physician endeavours to find out not only the actual condition of the patient, but also what will become of the patient. It is obvious that such a diagnosis can only be made by the method of clinical observation. Laboratory tests do not give a diagnosis, but merely signs which help us towards the real diagnosis. It is only after the clinical diagnosis has been established that such laboratory tests can be demanded to confirm, to develop, and even to correct certain *details* of the exploration of the patient. To attempt a diagnosis by collecting a series of routine laboratory signs, as this is usually done, is doomed to failure because in that procedure of the "diagnostical clinic" the directive line resulting from the consideration of the patient as a whole is neglected.

Armed with that precise diagnosis therapeutic handling has greater chance of success. Neo-Hippocratic medicine considers all medical or internistic therapeutic agents—psychical, dietetic, chemical, biological, and physical—and applies them according to the indications of the individual patient under severe control of the continuous diagnosis of the person. Thus one-sided applications of therapeutic agents, and particularly applications without continuous diagnostic control of the internist, are rejected. This neo-Hippocratic method of "rational therapeutical constellation" increases the healing power of the contemporary internist, and helps him to navigate between the Charybdis and Scylla of the nineteenth century medicine, medical nihilism, and surgical radicalism. In fact, the first positive results of this new method of approach towards the patient is the avoidance of unnecessary operations.

Those who follow international medical literature realize the importance of the neo-Hippocratic movement in the whole contemporary medical world. These modern doctrines are unfortunately dealt with too theoretically and too dogmatically. By bringing neo-Hippocratic medicine on the level of the actual clinical handling, by linking it with the name of Harvey, who was not only an experimentalist but a thinker, Dr. Robert Hutchison has rendered a great service to our art and science.—I am, etc.,

A. P. CAWADIAS.

London, W.1, Nov. 1st.

"WHAT IS LIFE?"

SIR,—In reply to the question which Mr. Monsarrat asks at the beginning of his letter in your issue of October 31st I would refer him, for a recent and very well written statement of the mechanistic position in biology, to Professor Hogben's book on *The Nature of Living Matter*. This book certainly represents ideas which are still current among many biologists though Mr. Monsarrat may not have come into intellectual contact with them.

The rest of Mr. Monsarrat's letter makes me fear that my own letter of the previous week was not sufficiently explicit. The point which I wished to express was that, if we interpret a living organism as "matter," whether dominated by a mysterious "vital principle" or not, we inevitably fail in the scientific interpretation of life. The use of the conception "matter" implies that we can legitimately separate in thought the events in a living organism from those in its environment, just as we ordinarily do in our conception of a machine. In a sense, we are constantly making this separation; but close examination shows that in so far are we do so we are unable to represent to ourselves the orderliness in biological phenomena. The fact that physicists are finding that even in what has hitherto been called the inorganic world this separation cannot ultimately be made strengthens this contention greatly. But the step which they are taking amounts to an abandonment, except as a very useful, and indeed necessary, provisional idea of the conception of matter as self-existent substance and the substitution, as Planck has put it in the statement which I quoted, of the conception of wholeness taken from biology.

As regards the relation of philosophy to [illegible] think that Mr. Monsarrat must have overlooked [illegible] I said in the first paragraph of my previous [illegible]

I am, etc.,

J. S. [illegible]

Oxford, Oct. 2nd.

THE TEACHING OF PSYCHOLOGY

SIR,—I share with Sir Robert Armitage admiration of the teaching record [illegible] Hospital in recent times, the more so [illegible] taught there by that superlative clin[illegible] Savage, to whom he refers. It is not

however, to say that Bethlem Hospital was "the pioneer of teaching in the subject."

Dr. Battie of St. Luke's Hospital gave some lectures in 1753 to pupils who attended the hospital. This can only be regarded as a sporadic outbreak. It was Esquirol of Paris who first taught the subject successfully at the Salpêtrière in 1817, and attracted medical men from all over Europe. He ceased to lecture when he went to Charenton in 1825. Among his first pupils was Sir Alexander Morison, who became visiting physician to Bethlem Hospital in 1835. Sir Alexander started to lecture in London on February 9th, 1826. He, however, gave practical instruction only for the first time in London to two or three pupils at the Middlesex Asylum at Hanwell in 1840, and two years afterwards he lectured at Bethlem Hospital from 1842 till 1852. Dr. Conolly gave an excellent and complete course of lectures at Hanwell from 1842 till 1847. Dr. Sutherland about this time also gave practical lectures at St. Luke's Hospital. By 1870, however, only Dr. Sankey of University College and Dr. Blandford of St. George's gave lectures in London—the former at Camberwell House. The position in Paris, which had started so well, was even less satisfactory. Lasègue lectured successfully from 1862 till 1866, after which official instruction ceased to be given. Sir George Savage was appointed physician to Bethlem Hospital in 1878, after Dr. W. Rhys Williams, who had delivered some lectures at St. Thomas's Hospital, and since then lectures have been continuously given by a series of distinguished teachers till the present time, when a complete course of instruction for the Diploma in Psychological Medicine is given.

Edinburgh has the longest continuous record of tuition in this subject of any medical school. Sir Alexander Morison started to lecture on mental diseases in Edinburgh on November 9th, 1823, over two years before doing so in London. He had at first an audience of only six persons, and his course consisted of nine lectures. He, with the help of his son, lectured continuously till 1852. Dr. Skae of the Royal Hospital at Morningside took over the lectureship in the following year, and lectured for twenty years. At Skae's death in 1873, Professor Laycock, who had also been lecturing on the subject for fourteen years in the University, began to lecture at Morningside. He died after three years, and was succeeded by Professor Grainger Stewart. In 1879, however, that great clinician Sir Thomas Clouston was appointed lecturer on mental diseases to the University of Edinburgh, and he continued to lecture for about thirty years.

It would thus seem that Sir Alexander Morison, imitating Esquirol, was the first to lecture specially on mental diseases in Great Britain. In Edinburgh, where he first lectured, there has not been a hiatus in the teaching of this subject for 107 years.—I am, etc.,

GEORGE M. ROBERTSON.

University of Edinburgh, Nov. 2nd.

THE PITUITARY IN THE ETIOLOGY OF CANCER

I read with the greatest interest Dr. ... on "The role of the pituitary in the ... er" (October 31st, p. 794), and the ... I venture to offer is by no means ... ure and does not affect his main con... de with the object of pointing out what ... a possible fallacy in the interpretation ... It applies equally to the explanation ... s of the Zondek-Aschheim reaction in ...

In commenting on the fact that Zondek has shown that in 15 per cent. of 118 cases of malignant disease the anterior pituitary hormone could be detected in the urine, he says: "In other words, in neoplastic disease anterior pituitary activity is increased to an appreciable degree in a significant proportion of cases." This is certainly a legitimate deduction, but it is not the only, nor, it seems to me, the most logical deduction. I suggest that it is reasonable to regard the hormone found in the urine as evidence that a certain proportion of the hormone, produced in amount adequate for the normal requirements of the tissues, is actually excreted unused because certain cells are incapable of utilizing or absorbing it. The effective action of a hormone does not depend only on the normal functioning of the gland producing it; the factor of the sensitiveness of the cell on which the hormone is intended to act, its ability to absorb the hormone, and, so to speak, interpret its message, must also be considered.

Sensitiveness to hormonic influence must, I think, be regarded as an essential function of any normal cell, comparable to its secretory, metabolic, or any other function. In malignant disease there is a failure of physiological function to a degree proportional to the degeneracy of the cell. If there is any considerable mass of cells so degenerate as to be partly or entirely incapable of absorbing the hormone it would be likely that the unused part of the hormone would be excreted unchanged. In a paper entitled "A theory of cancer"[1] I discussed the sensitiveness of the cell to what I called "the co-ordinating hormone," and, in the original draft of the paper ventured to prophesy that the unused part of the hormone might some day be detected in the urine.

The presence of anterior pituitary hormone in the urine in malignant disease and in pregnancy is not necessarily evidence that the hormone is being produced in excessive amounts; it is only evidence that more is being produced than is being absorbed.—I am, etc.,

Leicester, Nov. 1st. T. C. CLARE.

RHEUMATOID ARTHRITIS

SIR,—The correspondence evoked by the letter of "Crippled" in your issue of October 3rd tempts me to commit the statement that only by adopting some constructive hypothesis can we hopefully essay the task of solving the riddle of the etiology of rheumatoid arthritis. The late Dr. Strangeways once said to me, "Neither in my lifetime nor yet in yours will the cause of rheumatoid arthritis be discovered." This attitude of mind, however, is altogether too pessimistic.

Theoretically, the logical method of attacking a scientific problem is to conceive an hypothesis, to disprove it if need be, and begin afresh with both negative and positive data on which to work. The hypothesis which I venture to submit has *treatment* as its essential objective, and briefly amounts to this: the rheumatoid state is conceived to be comparable to that of a nation engaged in war, whose political and internal economy is dislocated by the prodigal and unrestrained activities of profiteers.

If this simile is allowed, the two problems which emerge are these: What are the influences which tend towards a state of war, and what is the nature of the profiteering? In regard to the former, it must be understood that just as there are nations to-day so placed that, given the necessary stimulus, the unhappy state of war may obtain at any moment, while there are others so situated either territorially or stabilized as the result of past and present policy, temperament, etc., that they are unlikely to be entangled in warfare, so there are individuals who will never be affected by rheumatoid arthritis, and others who, alas! will. The reasons given by Dr. Neligan (in his

[1] *Lancet*, 1920, ii, 1298.

letter published on October 17th) why women are more prone than men to be beset by a combination of physical and mental stress are in themselves quite sufficient to account for their greater predisposition to rheumatoid arthritis, but it is unlikely, as in international affairs, that the combination of factors which predispose to a state of war is a standard one. Turning to the question of profiteers, potential profiteers in the nature of streptococci are always with us, but, even given a state of war, the problem as to the evolution of potential profiteers to the condition of active profiteering has still to be established.

According to this hypothesis, a combination of factors as yet improperly understood conspire in a predisposed individual to lower his immunity and permit organisms of a low grade pathogenicity to gain access to the blood stream, and that these not only further disorganize an already stressed metabolism and give rise to further constitutional disturbance, but, possibly activated by some sensitizing agent, make, as it were, a corner in joints. That systemic disturbance is not mere fantasy is proved by the occurrence of pyrexia, tachycardia, thyroid enlargement, enlargement of the spleen, and even carditis and subcutaneous nodules, in differing percentages.

This hypothesis is useful (to me, at all events) in that its conception presents problems for research which are likely to be of utility in treatment—for example, in the adjustment of such biochemical obliquities as a deranged blood count, achlorhydria, etc., as well as the more fascinating, though up to the present less profitable, explorations of the territories of diathesis and tissue affinity. It explains in some degree the relative importance of [illegible] pus, for if we assume, for instance, that streptococci play an important part in the production of rheumatoid arthritis, then how can we hope to eliminate them by merely removing a tooth or two when a corresponding number of feet of intestine may harbour proportionately greater numbers? Even were it allowed that our knowledge of the etiology of rheumatoid arthritis has not increased since Spender's time, yet the same cannot be said in respect of treatment as Dr. Douthwaite's able writings, for example, testify.—I am, etc.,

VINCENT COATES

Bath, Oct. 25th.

SIR,—With reference to Dr. Douthwaite's letter in your issue of October 24th, I should like to join issue with him when by his words, "Careful desensitization with any form of protein will, in the early stages of an allergic disease, tend to produce benefit, or even cure probably this accounts for Dr. Warren Crowe's happy experiences," he gives the impression that it is only in the early stages that the Warren Crowe treatment is efficacious. That his experiences are happy in the early stages I can vouch for, but it is not only in the early stages. Happy results are obtained in patients who have been crippled for years. But in these long-standing cases great patience is required, by both the patient and the doctor. One of the greatest difficulties encountered is that the patient has already been hypersensitized—either by her own toxins or by some other form of treatment.

If cases of rheumatoid arthritis could be treated by the Warren Crowe method before they had been hypersensitized by other forms of intervention there is little doubt in my mind that in the great majority of cases a cure could be effected. I, too, have yet to see the Warren Crowe treatment fail in an early case. I recognize that "early" is difficult to assess.

At the same time I am not suggesting that vaccine therapy is the only effective form of treatment. Any form of treatment which would raise the patient's state of health to a higher level might enable her to overcome the rheumatoid arthritis. The fault with most forms of treatment, in the active stages of the disease, is that they are too drastic, and so defeat their own ends by producing a further auto-intoxication and a greater state of sensitiveness. If the day comes when any other form of treatment can claim 100 per cent. successes (in the early stages) so much the better, but until then the clinics run on the Warren Crowe lines will probably continue to flourish.

It seems highly probable that "Crippled" is right when she suggests that rheumatoid arthritis may be cured by "mental healing." If "mental healing" will raise the patient's resistance sufficiently, why should it not succeed? I cannot, however, agree with her argument that, because it succeeds, therefore the rheumatoid arthritis is possibly functional.—I am, etc.,

F. E. GRAHAM BOWALIE

Hove, Oct. 26th.

SIR,—Dr. K. E. Fernie's letter in to-day's *Journal* gave me great pleasure, for I can endorse to the full his x-ray observation that a barium enema shows a greatly dilated caecum and ascending colon in nearly every case of rheumatoid arthritis. A bismuth meal shows the reason for this habitual overdistension to be persistent spasmodic constriction of the distal colon due to chronic catarrh (colitis). This catarrh is caused by putrefaction of the faeces, and it has been shown by McCarrison, and more recently by others, that deficiency of vitamin B is an important factor in permitting putrefaction in the bowel.

The intestinal tube is the great focus of infection in all toxaemic disorders, it is far more extensive and therefore far more important than teeth, tonsils, sinuses, etc. In fact, these latter infections are almost always secondary to intestinal toxaemia, which impairs all tissues and renders them liable to attack by microbes. Failures to improve rheumatoid arthritis by the mere removal of septic teeth, tonsils, etc., will continue until such time as the intestinal tube is universally recognized to be the main seat of toxic absorption is investigated by x-rays (bismuth meal and barium enema), and is made the basis of efficient treatment.

The greater susceptibility of females to rheumatoid arthritis fits in with their greater liability to severe forms of chronic intestinal stasis.—I am, etc.,

ALFRED C. JORDAN.

London, W. 1, Oct. 31st.

DENTAL SEPSIS AND CHRONIC ARTHRITIS

SIR,—Chronic sepsis, particularly dental sepsis, as a causative factor in chronic arthritis has been so stressed during these post-war years that it is a relief to find in the *British Medical Journal* three consecutive letters from doctors who do not believe it. Nevertheless, it cannot be doubted that there does exist a relationship between the two, although this be other than one of cause and effect.

If a differentiation is made between rheumatoid and osteo-arthritis one will find that each has its special dental lesion associated with it: in the former case this will be dental caries, and in the latter pyorrhoea. If this association be analysed it will be seen that there exists a definite relation between the joint and the dental lesion in each case. The age incidence is similar, both caries and rheumatoid arthritis being essentially diseases of youth and early middle life, increasing in incidence at puberty, while pyorrhoea and osteo-arthritis are more usual in the later middle years. The general build and

made up of the patients is similar; in the first case we have the asthenic type of individual, rather undernourished with a tendency to acidosis, and in the latter the sthenic over-fed person with a tendency to alkalosis. The morbid anatomy of the joints themselves shows characteristic changes which are comparable with the dental changes, allowing for the differences of environment; with rheumatoid arthritis and caries we get a destruction of bone, cartilage, and dental enamel, and with osteo-arthritis a hyperostosis, a hypercalcification of the enamel, and a laying down of calculus in the subgingival sulcus (the destruction of the alveolus being a secondary change subsequent upon the progress of the condition). All this points to a common origin, the examination of which may be useful in pointing the way to the discovery of the fundamental etiological factors of both.

It is my belief that not only are caries and pyorrhoea *antagonistic lesions*, but that the production of each rests upon a metabolic disturbance in which the endocrine autonomic system plays the predominant part; an imbalance in the one direction tending to bring about an acidosis, and in the other an alkalosis. On this threshold or diathesis, which will usually be congenital, the strains and stresses of life commence to act, be these physiological, psychological, or dietetic. It would seem probable that the threshold for caries and for rheumatoid arthritis and that for pyorrhoea and osteo-arthritis are the same; this would account for their respective associations, and (through the similar biochemical changes which would result therefrom) for the similar anatomical changes which come about, which would be in the opposite directions in the one or the other group. Then, as soon as *sepsis makes its appearance*, which must result from a pre-existing caries or pyorrhoea, a vicious circle would be formed, the sepsis lowering still further the efficiency of the endocrine autonomic system and making worse the arthritis. This would account not only for the successes attending teeth extraction, but also for the, in my experience, far more frequent failures.

This conception of the causes behind both the dental and the joint conditions (a tooth is also a joint) will explain the occurrence not only of the dental destruction but also of the chronic sepsis. It is recognized that the organisms concerned are in no way specific, but are those whose usual habitat is the mouth, but which in some altered circumstances have become parasitic; it is also accepted that the endocrine autonomic system comprises the defensive mechanism of the body, for the perfect working of which a balance between sympathetic and parasympathetic portions is essential; if then caries and pyorrhoea, and rheumatoid and osteo-arthritis, are due to an imbalance of this system it is easy to see why they are so frequently associated with chronic infection. An observation of Pemberton's is interesting in this connexion. He says:

"The writer has drawn attention to the fact that tissues, such as the tonsil, harbouring foci, may undergo marked transformation, losing their conspicuous characters and becoming nearly or quite normal following improvement in the arthritis from a well-planned regimen. These several considerations emphasize strongly the probability that focal infection may often be the result of a systemic imbalance as well as the cause of it."

From this it will be seen that even if teeth are removed as a simple method of breaking a vicious circle, this does not really constitute treatment for the arthritic condition, any more than the filling of a tooth cavity constitutes the final treatment of dental caries.—I am, etc.,

Bournemouth, Oct. 17th.

PAIN IN THE ARM AND A DEAD TOOTH

Sir,—In his letter commenting on Dr. H. W. Hills's communication in the *British Medical Journal* of October 24th, p. 749, Dr. Crookshank is as interesting as he always is. Knowing his great controversial abilities, in spite of his dig at the pathologist, I hesitate to cross swords with him; merely, as regards the pathologist, venturing to suggest that the habit of this worker of interfering with the more imaginative flights of the clinician is one of the causes of his unpopularity. But I do venture to protest against the advice that "when a patient is ill, we should not hesitate to put right all that is 'wrong' merely because we don't 'see' how *this can explain that.*" It reminds one so much of the road to success of Sir Joshua Tonsil in *Mrs. Dose the Doctor's Wife*. "And it generally ended in their having several other little things done. . . . And now Joshua got fifty guineas for each little thing he did." I have *indeed been surprised to find* with how many "cures" practitioners who follow Dr. Crookshank's advice are credited, but the edentulous, tonsillectomized, and appendicectomized patients still seek the doctor's consulting rooms.—I am, etc.,

Kensington, W., Oct. 31st. Harold H. Sanguinetti.

FOREIGN BODIES IN THE ALIMENTARY TRACT

Sir,—In his paper on the relation of foreign substances to the human body, in the *British Medical Journal* of October 24th, Mr. Gordon Bruce records some of the wanderings of swallowed pins and needles inside the human body. He does not mention, however, that such bodies may pass through the whole gastro-intestinal canal without causing any detectable injury. Some twenty-five years ago I was consulted about a female baby 1½ years old, on account of painful defaecation. Rectal examination revealed a needle (which I removed with ease), stuck point downwards into the wall of the rectum. The mother then remembered that, a few days before, she left some needlework unattended for a few minutes in the presence of her baby, and on her return missed the unthreaded needle. In reply to her inquiry, the little girl pointed to her mouth. As the baby seemed perfectly all right, the mother disregarded the baby's gesture. I saw the child again when she was a young lady of about 16 or 17, perfectly fit and well. I do not remember whether I published this case in a medical journal at the time, but I recorded it in a little book of mine, *Nursery Hygiene* (Baillière, Tindall and Cox, 1910, p. 109). Swallowed fish bones or sharp pieces of wood sticking in the rectum and causing painful defaecation are probably familiar to every practitioner.

I have also had an interesting case of the passage of three considerable-sized gall-stones per anum, in a woman who was so moribund that she was refused operation at St. Bartholomew's Hospital about five years ago. She has not had another attack of biliary colic since then.—I am, etc.,

London, W.1, Oct. 26th. W. M. Feldman.

ENZYMES *VERSUS* TOXINS

Sir,—With regard to my letter on the nature of viruses in your issue of October 17th, may I be allowed to amplify slightly one point? In referring to the differences in behaviour between enzymes and toxins, I said that one can hardly suppose that the latter can impose an altered mode of functioning upon a cell. Probably this is true; but I had forgotten one instance, which *appears* to provide an exception. In an investigation on the nature and specificity of Negri bodies some years ago Acton and

Harvey (*Parasitology*, 1911, iv, 255) stated that they had been able to find similar bodies in animals which had been inoculated with viper venom, and also with an emulsion of *B. pyocyaneus*. Accepting these observations, the following explanation may perhaps be offered.

Toxins, as generally designated, may be, really, either or both of two things: (1) true toxins—that is, some specific, chemical substances produced as a result of metabolic activity; or (2) the particular enzymes which function in producing such substances. The latter would be the factors inducing a change in the metabolism of the affected susceptible cells. Compare, for example, the cases of rabies virus and snake venom. Both are produced by buccal glands (by epithelium of epiblastic origin, like the nervous system), and it is not difficult to consider that in the latter case, together with the actual secretion of the poison gland, there may also be some of the enzyme which has produced it. The action of the enzyme in causing the metabolism of the susceptible cells to function abnormally would naturally require a much longer time than that of the poisonous substance itself. It is not without significance, I think, that Acton and Harvey found that the only two out of twenty guinea pigs which showed Negri bodies, after inoculation with minute doses of venom, were the only ones which lived forty-eight hours or more. It is also possible that in long-delayed effects of bacterial toxins—for example, tetanus toxin—a similar double set of factors may be operating.—I am, etc.,

Walton-on-Thames, Oct. 26th H. M. WOODCOCK.

CHANGES IN THE GUINEA-PIG EMBRYO PRODUCED BY SCORBUTIC DIET

SIR,—The pathological anatomy of adult and infantile scurvy has received the attention of many investigators, so that both the macroscopical and the microscopical appearances are now well known. Characteristic abnormalities of the long bones at the costo-chondral junctions and at the epiphyseal lines are especially well recognized.

No investigations have apparently been made on the effects of scurvy on the embryo, since no reference to such work can be found in the literature, with the exception of that published by myself.[1]

Experiment has convinced me that "subacute scurvy" can be detected in the embryo as early as ten days after the mother guinea-pig is fed exclusively on a scorbutic diet. It was noted that, when fed on a scurvy-producing diet, a great many pregnant guinea-pigs died earlier than those which were not pregnant. Post-mortem examination in such cases showed advanced scurvy and a haemorrhagic condition of the embryos. I found that on a scorbutic diet pregnant guinea-pigs showed signs of scurvy earlier than guinea-pigs that were not pregnant.

I found, further, that of two pregnant guinea-pigs fed on a diet of bran, oats, and autoclaved milk, one aborted fourteen days and the other fifteen days after the special feeding was begun. It was difficult to determine the exact age of the embryos, but in both cases they were within two or three weeks of full development.

Eight other guinea pigs in a more advanced state of pregnancy had stillborn embryos after being fed on a scorbutic diet for thirteen days. All the embryos showed lesions characteristic of scurvy.

A suggested inference from these experiments is that embryonal scurvy may well be the cause of many abortions and stillbirths in the case of the human subject. Many cases of maternal morbidity *may* be due to scurvy-producing diet. It is well known that there are few abortions or stillbirths or cases of infantile scurvy in localities where mothers, otherwise healthy, live on natural foods.—I am, etc.,

Montreal, Canada F. M. WELLS, D.D.S.

[1] *Scurvy Tell-tale in a Sound Body*, p. 65. Desbarats Printing Co., Montreal, 1926.

THE TERM "CONGENITAL"

SIR,—I cannot agree with Dr. Feldman that the term "congenital" means "born with." Its true meaning is "generated with"—that is, "conceived with." The term applies to the fertilized ovum, which henceforth develops in a manner peculiar to itself.

I have no objection to the word "intra-natal" as applied to infection acquired during the process of birth; but if we are confronted with a child, aged 7, developing interstitial keratitis due to syphilis, we cannot be sure whether the infection was acquired *in utero* or at birth. The term "connatal" is therefore suggested to include both these contingencies; in either case there has been an acquired infection.

As a contrary instance I would cite Little's disease. If this is due to injury to the brain at birth then it is an intra-natal disease (belonging to one subdivision of connatal diseases). If, however, it is due to defective development of certain brain convolutions, then it requires to be reclassified as congenital. (There is here no question of infection.)

The intention, therefore, is to apply the term "connatal" to the diseases brought about by the accidents, including infection, that may happen to the fertilized ovum during the processes of gestation and of labour. The whole of these processes are necessary to bring about nativity.—I am, etc.,

Dagenham, Oct. 24th M. MELGRAVE.

Obituary

ALEXANDER WILSON, F.R.C.S.

Consulting Anaesthetist to Manchester Royal Infirmary, Surgeon to St. Luke's Hospital, Manchester

We regret to announce the death of Mr. Alexander Wilson of Manchester, which took place on October 23rd, after an illness of a few weeks' duration. He was born on August 6th, 1860, in Manchester, where his father was then in practice. As he was not of robust physique he was sent at an early age to live with Scottish relations at Lockerbie, and attended the Dryfesdale parish school there until 1872, when he returned to Manchester. After finishing his school work he entered Owens College for medical training, qualifying in 1883 with the London Conjoint Diploma. He served as house-physician and house-surgeon in the Manchester Royal Infirmary, as resident medical officer in its large convalescent hospital, and, finally, in a similar post at the Children's Hospital, Pendlebury.

Wilson married early in life, and went to Canada in 1885 with the idea of working there, but, finding things not promising or congenial, he soon returned home, and was for a time at Winchester. His friend William Thorburn then suggested that he should work for his F.R.C.S., and take up anaesthetics whilst doing so. He accordingly returned to Manchester, and was appointed an anaesthetist to the Royal Infirmary. This venture appealed to him so much that, although he passed the Fellowship in 1890, he decided to specialize in anaesthetics, and his genial and attractive personality and his ability and keenness for his work soon led to success. Walter Whitehead, G. A. Wright, and F. A. Southam were then the leading surgeons in busy practice and he was their first choice, because not only was he skilful, safe, and reliable, but he was always ready to lend a hand

anything that wanted doing during an operation, as, for instance, shifting a patient and getting him into the most suitable position for the surgeon, or to do any odd job he could turn his hand to. His experience with these junior men taught him many useful points about the conduct of an operation, and he was most helpful to juniors during their first surgical work by giving them little hints and by inspiring confidence to overcome the difficulties that so often present themselves during operations. He worked a great deal with Walter Whitehead in his early tongue operations on private patients, and devised a simple means of changing the position of the patient from that of lying down during the administration of the anæsthetic to the erect one during removal of the tongue to prevent blood from entering the larynx. This was the use of a common kitchen rocking-chair, and was very effective. After twenty years on the salaried staff of the Royal Infirmary, he was invited to become honorary anæsthetist and to direct this department of the hospital, which required the regular attendance of several men.

Early in his career, in the year 1890, Wilson joined the honorary staff of St. Luke's Hospital for Venereal Diseases, and remained in active work there until his health broke down a few months ago. He always had an intense sympathy for many of these patients, and they felt that they had a friendly adviser in their trouble. His association with this hospital and its work did a very great deal towards keeping its usefulness and need before the general public, and marked him out as the most suitable man to take charge of the venereal department at the Manchester Royal Infirmary when this was opened in 1917 as part of a national scheme organized by the Local Government Board. He continued in charge of this work for many years after he had reached the age limit of sixty for members of the staff in the active service of the hospital.

[illegible] commencement of the war he was attached to the 2nd Western General Hospital with charge of [illegible] and later, for twelve months, had its [illegible] well. He was very successful as administrator [illegible] with full confidence and respect of all who [illegible] direction. He retired with the rank [illegible] in the R.A.M.C. (T.F.). A neat, [illegible] out man, he looked the colonel every [illegible] was known to many long after the war, [illegible] to use the title himself, as "the [illegible] appointed a Deputy Lieutenant of the [illegible] for his services.

[illegible] excellent teacher, and trained many [illegible] anæsthetists. He had a very sympathetic [illegible] was most considerate towards the feelings [illegible] about to anæsthetize. Many a household [illegible] gratitude the care he took to allay the [illegible] had to "have chloroform," and [illegible] person whom he treated as a child [illegible] intimate terms to-day. A more kindly, [illegible]ed, and Wilson will be missed by [illegible] cheering pleasure of his friendship. [illegible] articles on anæsthetic subjects, and [illegible] from this for Ashby and Wright's textbook [illegible] *Children*.

[illegible] the British Medical Association met in London in 1910 Mr. Wilson was vice-president of the Section of Anæsthetics, and when it met in Manchester in 1929 was vice-president of the Section of Venereal Diseases.

E. M. B.

Dr. James Ardern Ashcroft, late of Littleborough, Lancs, died at Derby on October 24th, aged 69. He retired from practice several years ago, and had been in poor health for the last two years. He was a native of Marple, Derbyshire, and, after studying medicine at the University of Edinburgh, graduated M.B., C.M. in 1885 and M.D. in 1892. Dr. Ashcroft was in general practice for about forty years in Littleborough, and had been a member of the British Medical Association for many years. He was buried at Shore Church, Littleborough, on October 27th, and many of his old patients were present at the funeral service. He leaves a widow, one daughter, and three sons, one of whom is a member of the medical profession, and succeeded him in the practice.

Mr. Edward Septimus Earnshaw Hewer, F.R.C.S., died on October 24th, at Stratford-on-Avon, after an illness which had lasted nearly two years. He was born in 1875, and received his medical education at St. Bartholomew's Hospital, where he was secretary and vice-president of the Abernethian Society. He qualified as M.R.C.S., L.R.C.P. in 1898. After holding the posts of house-surgeon at St. Bartholomew's, and of assistant house-surgeon at the Gloucester Infirmary, he obtained the diploma of F.R.C.S.Eng. in 1900, and three years later began practice at Stratford. His outstanding skill in surgery was increasingly recognized there, and early in 1908 he was appointed surgeon to the Stratford-on-Avon Hospital. During the war Mr. Hewer took charge of the Clopton War Hospital, and his services in that connexion were recognized later by the conferment of the O.B.E. He won widespread popularity as a generous friend, as well as a highly skilled surgeon, and a large number of his medical colleagues from the surrounding district attended the memorial service.

Medical men throughout the country will regret to hear of the sudden death, on October 30th, after an operation, of Mr. J. Bernard Lamb, for over forty years the secretary of the London office of Epsom College, from which post he retired on pension only a month ago. Mr. Lamb had devoted his life to the furtherance of the Royal Medical Foundation attached to Epsom College, and his signature at the foot of appeals for funds must be familiar to great numbers of medical practitioners. During his tenure of office he saw the subscriptions increase from some £3,000 per annum to more than double that amount. To him the work was a hobby as well as a duty.

We regret to announce the death of Professor Guido Holzknecht of Vienna, a pioneer in roentgenology, and author of a standard textbook on radio-diagnosis, at the age of 58. Some months ago he had undergone amputation of the right arm for malignant disease due to *x* rays.

Medico-Legal

USE OF THE TITLE "DENTAL SURGEON"

In the Court of Appeal, on October 29th, before the Master of the Rolls (Lord Hanworth), Lord Justice Lawrence, and Lord Justice Romer, an appeal by the defendant, Mr. Wilfred Henry Weeks of Norwich, from the decision of Mr. Justice Farwell, in an action brought by the Attorney-General at the relation of the British Dental Association, was dismissed. The case turned upon the claim of Mr. Weeks, registered as "Dentist, 1921," to use the title "dental surgeon." The proceedings in the lower court, when Mr. Justice Farwell gave judgement for the plaintiff, were fully reported in the *British Medical Journal*, August 22nd (p. 359).

The Master of the Rolls, in dismissing the appeal, recounted the history of dental titles. Before 1878 persons were able to practise dentistry practically without any control. The Act of 1878 regulated the practice and qualification of dentists. The large majority of persons registered under that Act (in the proportion of 9 to 2) possessed no diploma or degree, and were admitted by virtue of *bona-fide* practice. As time went on, however, the proportion altered, and just before the Act of 1921 was passed there were on the *Dentists Register* 4,527 persons practising dentistry who possessed degrees and 428 (pre-1878 practitioners) without degrees. There was good reason, therefore, for taking a different attitude on the question of qualification when the latter Act

was passed. No doubt there was a desire to protect that large body of practitioners who possessed a degree or diploma, and therefore Section 4 (*b*) of the Act of 1921 provided that a dental practitioner was not to use "any title or description reasonably calculated to suggest that he possesses any professional status or qualification other than a professional status or qualification which he in fact possesses and which is indicated by particulars entered in the *Register* in respect of him." The defendant in this case claimed the right to call himself a dental surgeon, but in his lordship's view the section just quoted imposed a direct prohibition on that. The word "surgeon" expressed a distinct qualification, and the only issue was whether it suggested a qualification which the defendant did not possess. Mr. Justice Farwell had held the effect of the evidence brought before him to be that, while to many people the term "dental surgeon" had no particular significance, to a considerable number it had a definite meaning, and implied a person with a degree, licence, or diploma, and Mr. Justice Farwell had held that in those circumstances it was impossible to say that the use of the title "dental surgeon" would not reasonably suggest to many of the public that the defendant had some status or qualification which he did not in fact possess. The question must turn upon what the expression meant to those instructed and educated in such matters.

Lord Justice Lawrence and Lord Justice Romer concurred, and the appeal was dismissed. A stay of execution was granted for one month to enable the defendant to decide whether he wished to appeal to the House of Lords.

Mr. Grant, K.C., and Mr. J. R. Butterfield appeared for the appellant, and Mr. Gavin Symonds, K.C., and Mr. H. G. Robertson for the plaintiff. The court came to its decision without calling upon counsel for the plaintiff.

CHARGE OF FALSELY PRETENDING TO BE A REGISTERED PERSON

At the West Ham Police Court, on October 27th, Charles John Powell, aged 21, a hospital attendant, of Knollys Road, Streatham, was summoned for falsely pretending to be a doctor of medicine and surgeon, contrary to Section 40 of the Medical Act, 1858, which prescribes a penalty, not exceeding £20, for falsely pretending to be a registered person. He pleaded "Guilty."

Mr. E. Clayton, for the Director of Public Prosecutions, said that in March last Powell went to the offices of the Commonwealth and Dominion Line, and applied for a post of doctor or surgeon in a ship going to Australia. He was given a form to fill up, and it appeared that he went to a public library, looked up the *Medical Directory*, and selected the name of Duncan Pick, M.B., Ch.B., a doctor in Fifeshire. When he presented the form at the shipping office he had signed it in the name of Dr. Pick, and added Dr. Pick's qualifications. This, of course, was forgery, but the Director of Public Prosecutions, considering the whole circumstances, decided to proceed against him, not on that charge, but for a contravention of the Medical Act. Powell was posted to s.s. *Port Denison*, and went to Australia on the staff of that vessel as a doctor. He attended a number of patients, but nothing wrong was noticed. In August, two months after landing in Australia, he applied to the shipping company to be again taken on as a doctor, and he came back to England in the company's ship *Port Arthur*, on which again he attended a number of cases, but none of them of a serious character. At the end of the voyage he was told that he must report to the officials of the Immigration Department, but he did not do so, and, later, he sent a letter to the shipping company in which he stated that he was not Dr. Pick, and that he had gone to Australia hoping to obtain work there.

Detective Inspector Cockburn said that the reason why the defendant came back in the *Port Arthur* was to attend the captain, who was suffering from heart trouble, and the treatment which he gave him was really very good. The witness also explained that doctors who had taken their degrees in England were taken back in this manner to Australia free, and similar privileges were given to doctors in Australia who wanted to come to England to take further degrees.

Asked what he had to say in mitigation, the defendant pointed out that the ship he went in was one which did not generally carry a doctor, and that the ship he came home in never carried one.

The magistrate (Mr. St. John Morrow) said that the defendant did not seem to realize the seriousness of his offence. He had been engaged in sweeping out a nursing home, and suddenly he posed as a doctor and went on a six or seven weeks' voyage to Australia. He might have had several deaths on board, and if anything had happened to the people he treated, and they had died, he would have been charged with manslaughter. The case was, however, by the decision of the Director of Public Prosecutions, to be dealt with under the Medical Act, and he therefore fined the defendant £5 and 3 guineas costs, or, in default, thirty-one days' imprisonment.

Universities and Colleges

UNIVERSITY OF LONDON

University College: Department of Psychology

A course of twelve lectures, with practical exercises, on the administration of psychological tests in mental clinics and hospitals, will be given by Dr. W. Stephenson, Miss Constance A. Simmins, and Miss L. Grace Studman. The course will begin with a public introductory lecture by Dr. Stephenson, on Tuesday, November 17th, at 3 p.m. The day and hour for the continuation of the course will then be arranged to suit the convenience of those wishing to attend. Fee £1 11s. 6d. Inquiries may be addressed to the secretary, University College, Gower Street, W.C.1.

NATIONAL UNIVERSITY OF IRELAND

The following candidates have been approved at the examination indicated:

Third M.B.—*Part I (Pathology and Materia Medica)*: *M. F. Headon, †E. Isaacson, *C. F. E. Stanford, *J. L. O'Ferrall, *M. K. Mellett, †Con O'Leary, †J. F. Sullivan, †J. Jordan, G. Bialkin, P. A. Byrne, D. Coffey, C. Gray, D. J. Lawless, P. McMahon, Mary W. Meagher, R. F. O'Donnell, P. J. O'Ivan, G. F. Ryan, *Part II (Medical Jurisprudence and Hygiene)*: *J. K. Feeney, *R. Hayes, †J. Ready, *J. L. O'Ferrell, J. Fahy, E. Fleming, J. McSorley, P. J. O'Driscoll, P. G. Ryan, M. F. Sheehan. Exempted from further examinations in pathology: N. B. Higgins, J. J. O'Byrne, T. J. O'Donnell.

* First-class honours. † Second-class honours.

QUEEN'S UNIVERSITY OF BELFAST

Dr. J. S. Young, Reader in pathology in the University of Leeds, has been appointed to the Musgrave chair of pathology in Queen's University, Belfast.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a meeting of the Royal College of Physicians, held on October 29th, when the President, Lord Dawson of Penn, was in the chair, Professor H. R. Dean, Dr. Gordon Holmes, and Dr. J. P. Hedley were elected Councillors. Dr. K. D. Wilkinson was appointed an examiner in pharmacology and Professor R. T. Leiper an examiner in tropical medicine and hygiene. Dr. Raymond Crawfurd was re-elected a representative of the College on the Committee of Management of the Conjoint Board, and Dr. Comyns Berkeley the College representative on the Central Midwives Board. The President announced that the Council had appointed Dr. Robert Cruickshank of Glasgow University to be Milroy lecturer for 1933, and that Professor Edward Mellanby had accepted the office of Croonian lecturer, 1933. The appointments of Mr. D. H. Patey as Streatfeild scholar and Mr. F. E. Pitt-Payne as Jenks memorial scholar were also announced.

Membership

The following candidates, having satisfied the Censors' Board, were elected Members of the College.

Frederick Gerard Allison, M.D.Manitoba, James Hilton Bentley, L.R.C.P., Trevor Laurence Bomford, M.B.Lond., Rupert Pritchard Picton Davies, M.D.Lond., Laurence Bedford Elwell, M.B.Sydney, Maurice Rolfe Vickers Ford, L.R.C.P., Ivor John Franklen-Evans, M.B.Camb., Frank Alfred Gaydon, M.B.Lond., Isaac Gordon, M.B.Lond., Ram Kumar Goyal, M.B.Punjab, Richard Fairfax Fukuno Grace, M.D.Ed., Mohan Lal Gujral, M.B.Punjab, Arthur Sandford Hoseason, M.B.Lond., Esther Margaret Killick, M.B.Leeds, Frank Patrick Lee Lander, M.B.Lond., Mahomedali Ladhabhoy Mistry, M.D.Lond., Francis Alan Richards, M.B.Camb., Mahmoud

Saleh Eldin, M B Cairo, Henry Armand Hugh Selbourne, M B Lond., Sarah Shore, M B Lond., Felix Smith, M D Birm., Raghubansa Kishore Tandon, M B Lucknow, Shripad Shivarao Ugrankar, M B Bombay, and Khushwant Lal Wig, M B Punjab.

Licences

Licences to practise were conferred upon the following candidates, who have passed the Final Examinations in medicine, surgery, and midwifery of the Conjoint Board, and have complied with the by-laws of the College:

R Ahmad, S S Alam, G. T. Allen, M. W. Allen, A. B. Anderson, A V Anderson, V Ascher, I J Ashley, Kathleen W Aylwin-Gibson, R Butler, L I Bannister, *P. S Bassalvi, E. H. S. Bebb, C. M Bell, L A R Berkley, J B Bishop, M Bloom, H. E Bonnell, J R Brasbrooks, I J Burke, I. E Burrows, H. W. Cowen, R V I Creet, C J N Davis, N. E. D. De Silva, A H. Dunkerley, B Dunkerley, Joanna M Egerton, A. G. Evans, M. Farooq, J W H Fox, S G French, J. H. L Gilmore, G P. Gladstone, I R Glover, P W Godfrey, A. J. B. Goldsmith, G H Greenway, *H N. Gregg, W. Hall, G. W. Hall-Smith, R A L Hammond, Margaret Hardwick, Sheila M Harper, Florence D Hawes, F Hilmy, L A. Hiscock, Nora A. Hodgkinson, P A Hubbard, Daisy G. Iliff, J. A. James, W. H G. Jessop, D E V Jones, E. Kaminsky, A A. Kidvai, Victoria H King, A W Langford, H. H Langston, N. R C Lansdell, B. Lawn, J Littlejohn, A. D Low, J M Low, R. S C. McDade, J. G. Madden, *G. S Malik, M. H. Masina, *Sosa Matthew, M T. Maung, C. F Mayo-Smith, S. G. Meanley, T. F. Miles, A. Miller, I D Monger, M. Myers, P H Nankivell, M. W. C Oldfield, W H. Owles, G I Partridge, R C T Pearson, T J. Phillips, P. Pringle, Dorothy M M Rees, L Rees, G. O. S. Reid, W. F. Richards, B Roberts, I C Robertson, P. Rosenfeld, M. G. Ross, J. T. Rowe, C Rutter, C R Sadler, I N. Samuel, Mary A. Saunders, G. Scott, *A Shafi, H Shoukry, A Shufleder, H. Simpson, K. Singh, R I G Smith, P Q M Spaight, *G. Steane, D. Stone, G L. Stroud, I Sutton, J T C Taylor, G W Thomas, H C. Wadge, W W Walther, R A. Wesson, H. G Williams, R N. H Williams, I P Williams, D S P Wilson, As L. Wingfield, J. M. Wingfield, C L R Wood, R B. D. Wright.

* M R C S. previously granted.

A supplementary list of Licentiates is being issued later for candidates whose examinations were not completed when the above list was compiled.

Diplomas in Public Health were also conferred, jointly with the Royal College of Surgeons, on the following candidates:

M Akram, E A Aslett, R. S Baindur, Eleanor M. Carless, R Cove Smith, J Cribbin, J H Dancy, E C. Downer, E. Grundy, P L Khosla, J R Macdougall, C. V. Macnamara, R. D Munshi, J L Newman, Ajit K. Sen, Amiya K. Sen, H. B. Swift, I. Taylor, S R Wilson

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The annual meeting of the Fellows and Members of the Royal College of Surgeons of England will be held at the College, Lincoln's Inn Fields, W C., on Thursday, November 19th, at 3 p.m.

Bradshaw Lecture

The Bradshaw Lecture before the Royal College of Surgeons of England will be given at the College by Mr. W. Sampson Handley on Thursday, November 12th, at 5 p.m.; the subject will be chronic mastitis. Fellows and Members of the College are invited to attend. Students and others who are not Fellows or Members will be admitted on presenting their private visiting cards.

BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

A special meeting of the council, attended by a large number of the Fellows and Members of the College and their friends, was held in Grosvenor House, London, on October 23rd, when the president, Professor Blair Bell, conferred the Honorary Fellowship of the College on Professor Paul Bar of Paris, Professor Essen Moller of Lund, Sweden, and the Right Hon. Lord Riddell in recognition of their services to obstetrics and gynaecology. Their Excellencies the French Ambassador and the Swedish Minister were present, and returned thanks on behalf of their fellow-countrymen.

The following were admitted to the ordinary Fellowship of the College: Margaret Basden, Frank Cook, Joseph Bernard Dawson, Samuel Walter Maslen Jones, Gordon King, Arthur James McNair, Ruth Nicholson.

The following Members were admitted: Michael Waldo Boom, Bulman, Reginald Lionel Downer, Amy Margaret Fleming, John Kennedy Rose, Margaret Salmond, Gerald Spence Smyth.

The quarterly meeting of the council was held on October 24th. Dr. Henry Russell Andrews was co-opted to the Finance and Executive Committee until the next annual general meeting. It was decided that, notwithstanding any resolution to the contrary, those who were invited to become Fellows and Members from Great Britain and the Irish Free State be allowed to accept this invitation up to the time of the annual general meeting in 1932. The secretary reported the conclusions reached at a round-table conference held the previous day with representatives of the Dominions concerning the election and relation to the College of Fellows and Members in the Dominions. Important financial and other considerations were settled.

SOCIETY OF APOTHECARIES OF LONDON

New Regulations for Final Examination

The following additions have been made to the regulations for the Final Examination for the diploma of L.M.S.S.A. Lond.:

1. In future a separate examination in pathology and bacteriology (written, practical, and oral) will form Section I of the Final Examination. Candidates must take this section not later than the last part of Section II of the Final Examination, and will be admissible to it not less than twenty-four months after passing in anatomy and physiology, on production of the certificates laid down. (This regulation will not apply to candidates who pass, or become entitled to exemption from, the primary examination in anatomy and physiology before January 31st, 1932.)

2. Candidates who begin their professional studies after January 1st, 1932, will be required to complete the whole of Section II of the Final Examination (medicine, surgery, midwifery, and forensic medicine) within a period not exceeding twenty-five months. In cases where the period has been exceeded, it will be necessary for candidates to pass again in any subject or subjects in which they may have already satisfied the examiners, until this regulation is complied with.

The following candidates have passed in the subjects indicated:

Surgery.—H. W. Davies, G. Handelsman, M. Iddali, R. Perkins, Z. M. Pierpont, S. Ramarao.

Medicine.—S. J. Bellgard, L. F. Donnan, C. Morgan, Z. M. Pierpont, B. Rivlin.

Forensic Medicine.—V. R. T. Baylis, M. Ditton, L. F. Donnan, K. Malik, H. C. Pain, Z. M. Pierpont.

Midwifery.—V. R. T. Baylis, K. W. Bruce, G. A. Dingemans, L. F. Donnan, H. T. Giblin, H. G. Hind, J. L. King, F. C. Moll, T. D. Norton, E. M. F. O'Donovan, H. Owen, Z. M. Pierpont, F. A. Trowbridge, H. A. T. Wells, J. C. Williams.

The diploma of the Society has been granted to Messrs. H. W. Davies, L. F. Donnan, H. G. Hind, and Z. M. Pierpont.

Medical News

A Chadwick public lecture on "The outlook on tuberculosis—then and now," will be given by Sir Robert Philip at the Gateshead Town Hall on Friday, November 13th. The mayor of Gateshead will take the chair at 7.30 p.m.

The West Riding Association of Edinburgh Graduates will hold its annual general meeting and dinner at the Midland Hotel, Bradford, on Wednesday, November 11th. The meeting is at 6.45 p.m., and the dinner at 7.30. Professor D. P. D. Wilkie is to be the guest of the evening. The honorary secretary, Mr. Donald Watson, F.R.C.S., 33, Manor Row, Bradford, will be pleased to supply further information.

The annual dinner of the London (Royal Free Hospital) School of Medicine for Women will be held at the Savoy Hotel, Strand (Embankment entrance), on Thursday, December 3rd, at 7 for 7.30 p.m., with Lord Riddell in the chair.

The South-West London Medical Society will hold its first meeting of the new session on Wednesday, November 11th, at 9 p.m., at the Bolingbroke Hospital, Wandsworth Common, when Dr. S. A. Kinnier Wilson will give a lecture on "The diagnosis and treatment of epileptic varieties."

The Middlesex Hospital annual smoking concert, organized by the students in aid of the Cancer Wing, will take place at the Queen's Hall, Langham Place, on Friday, November 13th, at 8.30 p.m., with the Earl of Athlone in the chair.

A discussion on "The medical aspects of crime in fact and fiction" will take place at the meeting of the Hunterian Society to be held at Apothecaries' Hall, Water Lane, E.C., on Monday, November 16th, at 9 p.m. Fellows of the society may take non-medical guests, including ladies, to the meeting.

A combined clinical and pathological meeting of the West London Medico-Chirurgical Society will be held at the West London Hospital to-day (Friday, November 6th), at 8 p.m.

Dr. Erwin Wexberg of Vienna will speak on "Individual psychology and psycho-analysis in medical practice" at a special meeting of the Medical Society of Individual Psychology, to be held at 11, Chandos Street, Cavendish Square, W.1, on Thursday, November 19th, at 8.30 p.m. Visitors will be welcome on presentation of their cards.

The British Waterworks Association will hold its winter meeting on Thursday, November 19th, during the Public Works Congress, at the Agricultural Hall, Islington. At the afternoon session Dr. E. V. Suckling will read a paper on "The sterilization of water by catadyn silver," followed by a paper on "The cause and removal of earthy tastes in water," by Mr. B. A. Adams.

The Fellowship of Medicine and Post-Graduate Medical Association announces a three weeks' course in ophthalmology beginning on November 9th at the Royal Westminster Ophthalmic Hospital (fee £4 4s.). From November 16th to 28th a course in diseases of the chest will be given at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park (fee £2 2s.). A course in venereal diseases will be held from November 16th to December 12th at the London Lock Hospital, Dean Street (fee £2 2s.). From November 23rd to 28th there will be a course in proctology at St. Mark's Hospital (fee £3 3s.). The Infants Hospital will hold an afternoon course in diseases of infants from November 30th to December 12th (fee £3 3s.), and during the same period there will be a course in dermatology at the Hospital for Diseases of the Skin, Blackfriars (fee £1 1s.). Free lectures will be given on Wednesdays at 4 p.m. at the Medical Society of London, 11, Chandos Street, Cavendish Square, by Sir Henry Gauvain, Mr. Tudor Edwards, and Mr. Cecil Joll. Lectures for the M.R.C.P. examination will be given at the same place on Mondays and Wednesdays at 8.30 p.m. by Dr. Maurice Cassidy, Dr. Roodhouse Gloyne, Dr. W. J. Adie, and Dr. Knyvett Gordon. Full particulars from the Fellowship of Medicine, 1, Wimpole Street, W.1.

The annual congress of the British Institute of Radiology will be held at the Central Hall, Westminster, on December 2nd, 3rd, and 4th. In association with the congress an exhibition of *x*-ray apparatus will be held in the same building under the auspices of the British *x*-ray industry.

Reference was made in our issue of August 1st (p. 219) to the facilities for post-graduate study available in Berlin to members of the medical profession in this country. A booklet in English has now been issued by the Kaiserin Friedrich-Haus für das ärztliche Fortbildungswesen giving full particulars of the English courses that have been arranged by the Dozentenvereinigung. This association of lecturers consists of about two hundred professors, docents, and directors of hospitals, and has at its disposal over 20,000 beds. The English courses are given all the year round, and diplomas are awarded, on application, to students who have completed at least four months' or three hundred hours' attendance. There are opportunities for free instruction and for appointments to internships in many of the medical and surgical clinics, but for these some knowledge of the German language is generally required. Arrangements for private courses may be made through the office of the Association (Luisenplatz 2–4, Berlin, N.W.6), to which all inquiries should be directed.

The new extension of the Richmond Royal Hospital, which includes a new operating theatre and *x*-ray department, was opened by the Marchioness of Cambridge on October 20th.

The September issue of the *China Medical Journal*, published monthly by the China Medical Association, is devoted to leprosy, and opens with an article by Sir Leonard Rogers on prophylaxis. He denounces the rigid compulsory segregation of all lepers, as soon as they are discovered, as being an impractical procedure in the vast majority of cases, and leading to the concealment of early cases. He commends the provision of a voluntary system of up-to-date treatment for early cases at clinics, and segregation of the more advanced cases in leper colonies where they can cultivate the land and produce most of their food. He stresses the importance of examining the contacts of all known infective cases, and providing efficient treatment. Dr. R. M. Wilson discusses the management and maintenance of a leper colony; the diagnosis of leprosy is reviewed by Drs. E. Muir and F. Reiss; while articles on treatment are contributed by Drs. L. F. Heimburger and N. D. Fraser. Much of this issue is devoted to a survey of the incidence of this disease in the three southern provinces of China, and also in Southern Yunnan, Swatow, Szechuan, and Manchuria.

The *London Gazette* of October 20th announces that the King has conferred the Edward Medal upon nineteen persons for conspicuous bravery in rescuing a miner from a fall of roof in the Hedley Pit, South Moor, county Durham. Among the recipients was Dr. Charles James Brookfield Fox, who had been summoned to amputate, if necessary, the miner's leg to expedite his release. It was found impossible to amputate in the restricted area, but Dr. Fox remained on the scene until the miner was rescued, and examined and treated him before sending him to the surface.

A full report of the fourth annual scientific meeting of the Medical Association of South Africa and the twenty-fifth South African Medical Congress, at Johannesburg, in September, is published in the *Journal of the Medical Association of South Africa* (*B.M.A.*) for October 10th, and indicates the great success that was achieved under the presidency of Dr. Francis Napier. Some account of the work of the sectional meetings and of the social functions appeared in our last issue at page 817. The hospitality of the Southern Transvaal Branch and its Divisions was highly appreciated by all who took part in the congress.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring *REPRINTS* of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediscra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams, *Bacillus Dublin*; telephone: 62559 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams, *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Anal Neuralgia

"NEURALGIA" writes: I should be grateful for any information on the cause and treatment of anal neuralgia. A man of 57, and his wife, aged 49, both suffer from this distressing malady. There is no evidence of piles, fissures or anything abnormal to be seen. The attacks frequently come on at night. Sitting on a hot-water bottle controls the attack. The pain comes on suddenly, is sickening in character, and just as suddenly stops. If it comes on during the night it invariably wakes the patient. Heat seems to be the only remedy, but it is uncomfortable and inconvenient to have to rise in the night to prepare hot water.

Persistent Mild Pyrexia

Dr. H. S. Burnell-Jones (London, N.W.5) writes: The answer to Dr. Thos. McCulloch's question (October 31st, p. 832) is, Yes. About 1912, Dr. Whittaker, head master of Taunton School, told me of a boy at the school who, after an illness, continued with a temperature above normal. The head master and the school medical officer decided that, as the boy appeared perfectly well, they would take the risk of sending him on a journey which he had to take. A day or two after the journey Dr. Whittaker received a letter from the boy's father (who was a doctor) saying, "I should have told you that my boy's temperature is always above 98.6° F."

Income Tax

Temporary Residence in the United Kingdom

"B. M." proposes to come to England on leave in April, 1932. He is naturally desirous of avoiding income tax liability, which, he understands, will attach to him if his stay in England exceeds six months. He inquires what would be the result if he spends, say, five months out of seven in the United Kingdom, the other two being spent in occasional absences on the Continent, and, also, whether absence in the Irish Free State or the Channel Islands would be as effective as absence in, say, France.

*** The six months' test applies to the aggregate of the periods of actual physical presence in the United Kingdom, provided that "B. M." does not maintain a residence available for his use during his temporary absence abroad. The Irish Free State or the Channel Islands would be as effective for the purpose of absenting himself from the United Kingdom as any other place outside the United Kingdom.

Cost of Indoor Assistant

"S. B." asks what deduction may be claimed for the cost of an indoor assistant.

*** It is impossible to answer this question categorically—so much depends on the circumstances. Probably the best way of dealing with the matter is to take the accommodation and domestic service into account in estimating what proportion of the total is expended on the professional portion of the premises, and to make an *ad hoc* estimate of the cost of the assistant's food, laundry, etc.

Loss Incurred on Visit Abroad

"F. P." attended a scientific meeting abroad, as an official reporter for certain journals. His total emoluments were £25 and his travelling expenses—£125. The inspector of taxes declines to make him any allowance for the resulting loss of £100.

*** The loss is allowable if it was incurred as a matter of business, and the question to be decided is whether "F P." made the journey in the hope of gain, or for some other reason; in the latter event, the receipts are a reduction effected in the cost of carrying out a private desire, and the transactions as a whole would not give rise to a claim for income tax relief. Various factors enter into the decision; for example, whether "F. P." has in the past earned profits by reporting congresses, etc.

Liability of Assistant

"E. J S." refers to an answer in our issue of September 26th last, and states that the inspector of taxes declines to accept the view that he is not liable to pay income tax on £91, being the amount paid by his principal to a third person for his lodgings. The inspector refers to the decisions in Cordy *v.* Gordin and Ferguson *v.* Noble.

*** "E. J. S" is liable on the £6 10s. paid to him towards the cost of gas and lighting; the matter in dispute is with regard to the £84 10s. paid to the proprietor of the rooms occupied by "E. J. S." In Cordy *v.* Gordin it was held that an employee entitled to receive a certain salary but liable to suffer a deduction therefrom for cost of board and lodging was liable to tax on the full amount of the salary before the deduction was made. In Ferguson *v.* Noble it was held that a cash allowance received in lieu of a uniform was liable to assessment. In our view the essential feature in both these cases is the liability of sums which were received in cash or which were as stated, and would have been so receivable but for a deduction provided by the agreement for service. They are in the same line as the leading case of Tennant *v.* Smith, and do not appear to be conclusive against "E. J. S." It is still sound law that a benefit received in kind is not assessable unless it can be turned to monetary account. If "E. J. S.'s" lodgings were selected to suit himself, so that in effect they were his choice, equity is heavily against him, and a favourable decision by the local commissioners might be difficult to obtain; but we consider that the technical merits of the question are with him.

LETTERS, NOTES, ETC.

Phimosis and Circumcision

Dr. E. Sutherland-Rawlings (late senior medical officer, London Lock Hospital, and assistant, Venereal Diseases Department, St. Paul's Hospital) writes: With reference to the recent letter in the *British Medical Journal* on circumcision, I should like to point out that the class of infant to whom circumcision is "an act of barbarism" must belong to the enlightened society who instruct their sons in the hygiene of a genital toilet. For the lower classes—those seen at venereal clinics, for example, where the stench of decomposed smegma makes the examiner sick—the advantage of the circumcised over the uncircumcised is apparent, more especially in such cases as the following: phimosis, balanitis, herpes preputialis, chancre of the prepuce, etc. In the *Lancet*, last March, I pointed out that penile chancres occurred more frequently in the circumcised than in the non-circumcised. Again, I have found that masturbation most often occurred in those cases with a mild degree of phimosis, and that in adults circumcision under local analgesia served as a cure for the complaint. Convulsions and fits in a child of 8 months was cured beyond doubt by a simple circumcision. I would suggest that all practitioners, especially in the poor localities, should urge circumcision, if only as a mild prophylactic measure against penile troubles later on in life.

"Bridgets and Virgins"

Dr. Harold Balme writes: In these days of ante-natal version for malpresentations the following verbatim account recently given me by a patient may not be without interest: "I went to see a doctor when I thought I was due, but directly 'e put 'is 'ands on me, 'e said, 'Good Lord, woman, your baby's coming the wrong way; you must go off to 'orspital at once and 'ave it turned.' So off I went, and as soon as I got there they took me into a theatre and gave me chloroform. And there were two other ladies besides me what 'ad got their babies the wrong way, but the doctors said that my case was rather different from theirs. Mine, they said, was a *bridget*, but the others was just *virgins*. . . . And my 'usband, 'e didn't 'alf carry on when 'e knew I 'ad to go into 'orspital. Do you know what 'e did, doctor? 'E just cried for two hours, 'e did, and then 'e went and 'ad 'is 'air cut, just to take 'is thoughts off."

CO_2 in Resuscitation

"F. B. R." writes: Apropos CO_2 as a respiratory stimulant, at a recent confinement, as the result of premedication of the mother, of instrumental delivery, or of some cause unknown, the child was born in a condition of partial asphyxia. Half an hour's effort to restore respiration proved ineffective, beyond producing a spasmodic inspiratory gasp at intervals. The baby appeared to have definitely decided not to remain. It then occurred to me to try the "Sparklet" apparatus, or, I should rather say, contrivance, which one carries in the anaesthetic bag. The result of discharging a little CO_2 in front of the baby's mouth at the moment of its making a rare inspiratory effort was instant and amazingly effective. The rhythm was started, and in a few minutes all anxiety had vanished. Admittedly there is nothing startlingly new in this phenomenon. I feel, however, that I am justified in relating the experience from the conviction that the average practitioner is unaware that he has to his hand a simple, inexpensive little CO_2 container, suggested by a Manchester anaesthetist and manufactured by the "Sparklet" people. I now feel it should have a place in every midwifery bag, and that it will save many an infant life.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 51, 52, 53, 54, 55, 58, and 59 of our advertisement columns, and advertisements of partnerships, assistantships, and locumtenencies at pages 56 to 57.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 207

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

405 Thrombo-phlebitis Migrans in Scarlet Fever

J. B. ELLISON (*Brit. Journ. Child. Dis.*, July–September, 1931, p. 207), who reports two illustrative cases, remarks that inflammation of the veins is a very unusual complication of scarlet fever, only a few cases having been recorded by Schamberg and Koimer, Rolleston, and Hunekens and Siperstein. His patients were two boys, aged 6 and 10½ years respectively, who at a late stage of a mild attack of scarlet fever developed the condition described by Moorhead and Abrahamson as thrombo-phlebitis migrans. The characteristic features are (1) lesions disseminated in time and space, small lengths of superficial vessels being first attacked; (2) phlebitis of the lungs and abdominal viscera; and (3) a favourable prognosis in spite of a prolonged course. Complete recovery in both cases followed within five weeks from the onset.

406 Pulmonary and Laryngeal Tuberculosis

M. AUBRY and L. BRODIEZ (*Presse Méd.*, August 26th, 1931, p. 1267) from a study of some cases conclude that there is a more or less direct correlation between pulmonary and laryngeal tuberculosis, and that this complication presents two diametrically opposite types: the infiltration-ulceration type with caseous evolution, and the fibro-congestive form which tends to ultimate fibrosis. The first form, the classical and most common, has been fully described by numerous authors, and its characteristics are summarized. The second type is distinguished from the first by the fact that often the laryngeal lesions are the first manifestations of the pulmonary complication. The cough is very slight, and the expectoration, whether scanty or plentiful, contains few bacilli. In contrast with the caseous form, the dysphonia and dysphagia are slight; dyspnoea appears relatively early, and may be very accentuated. The laryngeal lesions occur particularly on the ventricular band, and often the whole hemilarynx is affected. Though the band, cords, and arytenoids are greatly infiltrated, mobility is usually conserved. The general state is always unaffected. The lungs reveal very characteristic signs, which are described. The prognosis is much more favourable than in the caseous form. The lesions can be treated directly without fear of causing exacerbations, and in this fibro-congestive type, diathermy and galvano-cauterization produce good results. A typical case is recorded, and, in conclusion, the authors state that prognosis depends rather on the caseous tendency than on the extent or actual activity of the lesions.

407 The Cardiac Output in Complete Heart-Block

L. B. ELLIS and S. WEISS (*Amer. Journ. Med. Sci.*, August, 1931, p. 195) discuss the condition of the cardiac output and the peripheral circulatory mechanism in complete heart-block. They investigated five patients with this condition, two of whom had no functional disability; in two cases the symptoms were moderate, and in one the general disturbance was pronounced. It was found that the two patients with no functional incapacity and no arterio-sclerosis had normal arterial blood pressures, while the other three had systolic hypertension. In the absence of cardiac failure the venous pressure was normal. In the four patients with no circulatory failure during rest, normal values were found for the cardiac output estimated per minute; the outputs for each beat in these patients were, however, increased 40 to 50 per cent. above the normal. In the fifth patient, who suffered from circulatory failure, even in bed, indirect evidence of a decreased blood flow was obtained. The circulating blood volume was reduced in four patients, and is not mentioned in the fifth. Basal metabolic rates in the lower part of the normal range were present in four patients, while in the fifth the rate was 20 per cent. below normal. The degree of elevation of the lactic acid and the changes of blood gases following exercise were normal in one patient, who had good functional capacity. The authors conclude that the increased stroke volume of the heart, the systolic hypertension, the reduced blood volume, and, possibly, the somewhat lowered basal metabolic rate, may be considered compensatory responses tending to maintain a constant and adequate blood supply to the tissues during the prolonged diastolic pauses consequent upon the slow heart rate. They add that the symptoms of patients with heart-block are of two types: (1) those of congestive or anginal heart failure, resulting from myocardial degeneration; and (2) the Stokes-Adams attacks, probably due to insufficient cerebral circulation attributable to the inability of the heart to respond to the demands of exertion, or to alterations in the peripheral circulatory adjustment, or, most probably, to a local decrease in the irritability and responsiveness of the ventricles with periods of ventricular asystole. Complete heart-block is therefore compatible with normal life, and the prognosis as regards health and life depends mainly on the presence or absence of myocardial disease.

408 Post-vaccinal Myelitis

T. W. BROCKBANK (*Journ. Amer. Med. Assoc.*, July 25th 1931, p. 227) records a case in a boy, aged 6 years, in whom the prodromal symptoms began on the thirteenth day after vaccination. Complete spinal anaesthesia developed up to the level of the ninth dorsal segment, with accompanying paralysis, and was still present six months after the onset. The case is remarkable in that the acute inflammatory lesions of the nervous system reported as occasionally following vaccination have usually presented the clinical symptoms of encephalitis or polio-encephalitis, while in cases with paramount spinal cord involvement the sensory impairment has been negligible or transient.

409 H. GOUNELLE (*Paris Méd.*, August 15th, 1931, p. 144) reports a case of lumbo-sacral myelitis in a soldier aged 21, which occurred a fortnight after revaccination. Complete recovery ensued in six weeks.

410 Agranulocytic Angina

R. C. LOGEFEIL (*Minnesota Med.*, August, 1931, p. 696) refers to the increasing number of cases of this syndrome, its grave prognosis, and high death rate. In one series of 75 definite cases, only 16 patients recovered (20.25 per cent.); in another series of 150 cases, the mortality was 82 per cent. The condition is characterized by acute sore throat, fever, and prostration; this is followed by a bleeding gangrenous ulceration of the mouth and pharynx, with a pseudo-diphtheria! exudate. The liver, spleen, and occasionally, the lymph glands are enlarged; terminal pneumonia follows, accompanied by severe leucopenia with few or no granulocytes, and a relative lymphocytosis. Sometimes there may occur ecchymosis, secondary anaemia, necrotic ulceration of the oesophagus, intestines, and genitals, jaundice, coryza, multiple abscesses, polyarthritis, and mental torpor, but leucopenia and angina are the only constant symptoms. The disease attacks apparently healthy persons, usually middle-aged women, though some patients have had previous illnesses. Bacteriological and post-mortem examinations have proved unsatisfactory, but haemolytic streptococci are present frequently. Logefeil reports a fatal case in a woman, aged 29, who had febrile sore throat and malaise a week after an alveolar abscess had been opened; she had had a similar attack, with leucopenia, a year previously. The angina increased, and diffuse broncho-pneumonia ensued. A blood count showed 2,500 leucocytes, 20 per cent. granulocytes, and 80 per cent. lymphocytes. The soft palate

sloughed. Blood cultures were negative. Transfusion produced only a transient improvement, and the patient died twelve days after admission. Logefeil concludes that agranulocytic angina or true agranulocytosis may be a definite bone-marrow disease. It may accompany severe sepsis, chronic infections, chemical poisoning, aplastic anaemia, and aleukaemic blood conditions. Absence of abnormal blood cells, severe secondary anaemia and haemorrhagic diathesis, with the presence of severe ulcerating angina, prostration, and terminal pneumonia, are characteristic of it, and aid the differential diagnosis.

Surgery

411 Perforated Duodenal Ulcer

W. C. WHITE and H. A. PATTERSON (*Annals of Surgery*, August, 1931, p. 242) comment on the remarkable frequency of acute perforations of duodenal ulcer in men as compared with women, and state that they are unable to account satisfactorily for this fact. In a large series of cases only 3 per cent. occurred in women, and there were fifty or sixty consecutive male cases. The majority of acute perforations occur in the third, fourth, or fifth decade, nearly 40 per cent. being in the fourth. There is usually an exacerbation of chronic ulcer pain before perforation ; this lasts from several hours to two weeks, and represents serosal involvement by the pathological process. This pain is constant, and is not relieved by food or alkalis. The cause of perforation is doubtful, a full stomach, sudden exertion, and excess of alcohol being possible factors. Treatment in the majority of early cases of acute perforated gastro-duodenal ulcer should consist in the simple closure of the perforation, with or without drainage. Of these cases it has been found that 60 per cent. to 65 per cent. remain free from gastric symptoms ; 10 per cent. to 15 per cent. require a gastro-enterostomy at a later date on account of pyloric obstruction. The remaining 25 per cent. of patients are free from symptoms, if they are careful as regards their diet and general routine. Partial gastrectomy in some of these cases is advisable as a curative measure. Primary gastro-enterostomy does not produce good results, but secondary gastro-enterostomy following pyloric obstruction after simple closure is a satisfactory procedure. In certain cases of acute perforated gastro-duodenal ulcer adequate closure may produce a pyloric occlusion on account of a large perforation, unusually extensive surrounding induration, or both ; in these cases an immediate gastro-enterostomy is justified. Careful closure, with the use of omental tomy [illegible]nt, will reduce to a minimum the cases in [illegible]ecessary. Pyloroplasty and partial gastrec- duodenal [illegible]e good results in cases of acute perforated

412 [illegible] Cure of [illegible]stric Ulcers

VAN DER VOORDT (*Bruxelles-Méd.*, [illegible] July 19th, 1931, p. 1127) records notes of thirty-fi[illegible] cases in which he has operated for the radical cure of [illegible]h of some of the results, in spite of the poor general hea[illegible] one case when patients, were highly successful, except[illegible] death on the delirium tremens developed, followed [illegible]ling a consider- eleventh day. A wide gastrectomy, incl[illegible] performed in able portion of the lesser curvature, wa[illegible] much of the each instance. This procedure removes [illegible]ber of subse- acid-secreting area, and diminishes the num[illegible] there is less quent peptic and jejunal ulcers ; in addition[illegible] As regards subsequent trouble from pain and gastralgia, [illegible] is attached the operative technique great importance [illegible]ated atten- to the necessity for the continuous concentr[illegible] of operation, tion of the surgeon and his assistants during the[illegible]t to finish and to the supervision of the case from start [illegible]portance of by the surgeon himself. The essential impo[illegible]struments, local anaesthesia, the exclusion of all crushing in[illegible]d d are all and the employment of reabsorbable threa[illegible] as tment has emphasized. Pre-operative vaccination trea[illegible]pear been abandoned.

413 Raynaud's Disease

A. M. GRAVES (*Amer. Journ. of Surg.*, July, 1931, p. 83) suggests various causative factors in Raynaud's disease, such as exposure, trauma, psychic exertion, sudden fright, and acute infections. It occurs most frequently between the ages of 18 and 30, and it is found that women are more frequently affected, the proportion of female cases being about 80 per cent. The onset of the disease is usually sudden, and of short duration, following exposure to cold in most instances. The disease may subside spontaneously, but the majority of cases remain remittently active. The characteristic symptoms are local syncope and asphyxia, and local or symmetrical trophic lesions, or gangrene. Local syncope is the term used to describe the blanching of a part which occurs most often in the fingers, toes, cheeks, ears, or nose. This condition lasts for varying periods of from five minutes to a few hours, and is liable to recur. This syncope is usually followed by a local anoxaemia, with temporary swelling or a cold sweat. If this condition persists the skin may become black and mortified, with desquamation of the epidermis. A period of hyperaemia may follow the syncope or asphyxia. If these phenomena persist, gangrene of the peripheral parts eventually results ; this is usually of a dry variety. In nearly every case there is a painful numbness, followed by a sensation of burning and tingling. Treatment in mild cases should be prophylactic, such as the wearing of warm clothing, the application of heat, or the removal to a warm climate. Small areas of gangrene should be allowed to demarcate and slough, but amputation is necessary for large areas. Good results have been obtained from surgery of the sympathetic system such as periarterial sympathectomy ; a modified sympathetic ramisection ; ganglionectomy ; excision of the second thoracic ganglion with the stellate ganglion and the intervening trunk ; and resection of the last cervical together with the first and second dorsal ganglia. Prognosis as to the life of an affected part in Raynaud's disease used to be poor, and amputations were frequent, but earlier diagnosis and a more satisfactory therapy have made it possible for an affected part to remain useful for many years in a good number of cases.

414 Diagnosis of Intracranial Tumours

D. L. BUTTERFIELD (*New York State Journ. of Med.*, August 15th, 1931, p. 1001) reports seventeen cases of intracranial tumours without the diagnostic sign of choked disk ; they came to his notice during a period of eighteen months. These consisted of fourteen brain tumours, one large cortical cyst of the parieto-occipital region, and two cases of pachymeningitis haemorrhagica interna. Notes on all, and illustrations of some, of the cases are given; these demonstrate that masses may be present in many sites, and of large size, without causing any choking of the disk, although other ocular signs may be present. In none of the cases was there any considerable intracranial pressure as shown by lumbar puncture. The author suggests that at least 15 per cent. of cases of intracranial tumours do not exhibit the classical sign of choked disk, and that consequently a diagnosis will often have to depend on the other two signs.

415 Gall-stones in the Common Bile Duct

E. S. JUDD and J. M. MARSHALL (*Arch. of Surg.*, August, 1931, p. 175) review 1,608 cases in which stones of the common bile duct were removed by operation, and point out that 1,120 of the patients were women and only 488 men. The youngest patient was 5 months old, and a fourth of the number were over 60 years of age. On an average the female patients came for treatment 5½ years earlier than the males. The most common symptoms of stone in the common bile duct are paroxysms of colicky pain, chills and fever, and jaundice. The stones may cause no symptoms for some length of time, but eventually there is irritation of the mucous lining of the ducts, which produces an inflammatory reaction with oedema round the stone, occluding the duct, and giving rise to biliary obstruction. Symptoms of sepsis,

followed by jaundice, will appear if infection and obstruction are present. In the cases under review 80 per cent. had a history of one or more attacks of severe biliary colic; 17 per cent. had dull pain in the epigastrium, and only 2.4 per cent. had no pain. Jaundice was present in 73.4 per cent. of the cases, with symptoms of sepsis, with chills and fever in 37 per cent. Gastro-intestinal disturbances with nausea and vomiting were common symptoms, and the majority of patients suffered from chronic dyspepsia. Diagnosis is aided by cholecystography, and the passage into the duodenum of a small soft Rehfuss tube to determine the possibility of obtaining bile through the tube, as is the case when the obstruction is a stone; in stricture or malignancy no bile can be recovered. Of the 1,608 cases reviewed stones were found both in the gall-bladder and the common bile duct in 63.5 per cent.; in 36.5 per cent. stones were only present in the duct. The spontaneous formation of a fistula between the gall-bladder and an adjacent hollow viscus occurred in 72 patients, the fistula in most cases being between the gall-bladder and the duodenum. Pancreatitis was an associated lesion in 26 per cent., and marked cholangitis in 4.2 per cent. of cases. Varying degrees of hepatitis and biliary cirrhosis were seen in the liver when the condition was of long standing. Operation, which consists of removal of the stones, should also include the removal of the gall-bladder when jaundice is not present or the operative risk is too great. In these cases prolonged drainage is indicated, even for as long as a year if necessary. In the series reported the mortality rate was 6.7 per cent., death being due to local or generalized peritonitis, pneumonia, haemorrhage, nephritis, and pulmonary embolism. In 75 cases there was recurrence, and in 55 stones were again removed from the common bile duct.

416 Typhoid Perforation of the Gall-bladder

A. WAJSMANN (*Thèse de Paris*, 1931, No. 407) states that while cholecystitis and perforation of the gall-blader in typhoid fever are well known in the adult, in the child these complications are much rarer. A search through the literature from 1835 to 1930 revealed only thirty-five cases of typhoid cholecystitis in the child, in fifteen of which (42.85 per cent.) perforation was anatomically proved. The onset of typhoid cholecystitis may take place in two different ways: either it may closely simulate intestinal perforation, and its true nature be only discovered by systematic examination of the biliary tract, or the symptoms at once point to cholecystitis with evidence of perforation. In perforation of the gall-bladder the interval of peritoneal tolerance is much longer than in the case of intestinal perforation. The mortality among children with perforation of the gall-bladder is 87 5 per cent. in the absence of operation, but, when an operation is undertaken, even late, recovery takes place in 62.5 per cent. Cholecystitis appears to be the best operation since it is the easiest to perform, can be completed in the minimum of time, and has the advantage of draining the gall-bladder and of preventing fresh infection of the intestine. The thesis contains the histories of sixteen cases in children aged from 5 to 13 years.

Therapeutics

417 Insulin in Malnutrition

R. D METZ (*Journ. Amer. Med. Assoc.*, May 2nd, 1931, p 1456) has found insulin an effective remedy in malnutrition. An increase in weight is noted after its use in the asthenic, under-nourished, and visceroptotic patient with an apparently intact carbohydrate metabolism; such patients benefited subjectively, and retained their added weight after the insulin had been stopped. Its general effects are obvious in an increase in the subcutaneous tissue, and a healthier appearance of the skin. The nervous system becomes more stable, and the mentality and outlook upon life brighter; there is a gain in strength also. The improved mentality is shown by an increase in ambition and determination, giving a markedly increased interest in life. With the patient in hospital on the usual general diet three doses of 10 units each are given before each meal on the first day, increasing by five units daily up to 20 and 30 units. For ambulatory patients the dosage is smaller, starting with 5 units twice a day, and rising to 20 units three times daily. Any occurrence of hypoglycaemic symptoms is controlled by the ingestion of sugar. The gain in weight resulting from the treatment ceases when the weight has reached the normal for the patient. The author records five illustrative cases.

418 Oxygen Administration in Cardiac Failure

Adequate transportation of oxygen from the lungs to the tissues is maintained by the normal heart, but in cardiac disease there is impairment of this function; the significance of this type of anoxaemia in cardiac failure is not clearly understood. A. L. BARACH and D. W. RICHARDS (*Arch. Int. Med.*, August, 1931, p. 325) review the literature relating to the production of symptoms of cardiac failure by deficiency of oxygen in the blood, and to the effects of oxygen administration in cardiac insufficiency. The difficulty in this treatment has been to keep patients continuously in atmospheres of high oxygen content for considerable periods. The present authors claim to have overcome this by using the Barach oxygen chamber. They record the results obtained in eight patients suffering from various forms of circulatory failure, with cyanosis, who were treated in a chamber containing 45 per cent. of oxygen for three to sixty days. Five patients who had congestive cardiac failure with arterial anoxaemia were benefited by an atmosphere containing a high degree of oxygen. Striking objective changes were: increased arterial oxygen saturation, with decrease of the cyanosis; diminished pulmonary ventilation; and rise in the carbon dioxide levels. Subjectively, there was relief from the dyspnoea and orthopnoea. Three patients experienced marked diuresis and disappearance of oedema while breathing a high concentration of oxygen. The oedema returned when the percentage of oxygen was lowered, and again disappeared when the oxygen was increased, as long as cardiac insufficiency was present.

419 Vaccine Treatment of Chronic Erysipelas

A. M. MEMMESHEIMER (*Münch. med. Woch.*, August 21st, 1931, p. 1438), during the last five years, out of twenty-two cases of erysipelas has observed sixteen in which the disease assumed a chronic recurrent character, the cutaneous symptoms being the most prominent. The condition was therefore frequently mistaken for other skin diseases. The great majority of these cases (12) occurred between the third and sixth decades, and mainly in women (13 cases). In such cases treatment by intravenous injections of a mixed vaccine composed of at least twenty different strains of pathogenic streptococci had a remarkably good effect. The doses consisted of 0.2, 0.3, 0.4, 0.5, and 0.6 c.cm. given every other day. In cases where the reaction was severe intramuscular injections were substituted, the initial dose being 0.5 c.cm., which was subsequently increased to 0.75, 1, 1.25, 1.5, and 2 c.cm.

420 Fumigation in Superficial Fungus Infections

S. AYRES, N. P. ANDERSON, and E. M. YOUNGBLOOD (*Arch. Dermatol. and Syphilol.*, August, 1931, p. 283), though claiming no originality for the idea of fumigation, suggest that insufficient attention has been given to fumigation as an essential measure to prevent the spread of superficial fungus infections—for example, those acquired by walking barefoot on infected floors of such places as gymnasia, swimming pools, athletic and country clubs. In America, it is stated, the habit of walking barefoot has so increased in recent years that epidermophytosis, or ringworm of the foot, has become epidemic. The local condition is best treated by an ointment containing 2 grams of salicylic acid, 4 grams of benzoic acid, and 30 grams of benzoinated lard, but experience has proved that it is useless to cure the local condition unless patients sterilize their shoes and stockings, bathmats, and the floors of bedrooms and bathrooms. The spores of such a fungus as epidermophyton may remain viable

on the ground for a year or more, but fumigation with a formaldehyde candle is a simple and effective method of sterilizing all the materials with which the infection has come into contact. A simple experiment to prove the susceptibility of the more common types of pathogenic fungi to the fumes of formaldehyde was made, infective material from active lesions, as well as from old cultures, being exposed for four hours to the fumes of a formaldehyde candle in a closed room. Fresh tubes of Sabouraud's medium which had been inoculated with the fumigated material remained sterile indefinitely, while the control tubes produced good growths in three or four days. Periodic fumigation of gymnasium floors and shower rooms is advised, in order to prevent epidemics of ringworm.

Ophthalmology

421 Early Treatment of Squint

E. K. HALLOCK (*New York State Journ. of Med.*, June 15th, 1931, p. 745) emphasizes the importance of early treatment in strabismus. The normal condition of muscle balance is present when, with the gaze fixed on a distant point, the eye is in focus, with the ciliary muscle at rest; the axes of the eyes are parallel; with the gaze fixed on nearer objects, the amount of accommodation required is proportioned to the distance between the object and the eye; and the amount of convergence is just sufficient to direct each eye to the object looked at. Binocular fixation is developed in early life, by a method of "trial and error"; if refractive errors are present in one or both eyes, it is impossible for both eyes to fix an object, and for that object to be clearly seen. The tendency is therefore for the better eye to fix the object, and for the worse to be allowed to deviate. Since the vision of the deviating eye is now a hindrance, the brain begins to disregard its image, and eventually a condition of disuse amblyopia results. Refraction, under atropine, should be undertaken at an early age, and glasses be prescribed. There will still be a tendency not to use the subnormal eye, and the sight of the good eye should therefore be obscured by special glasses for a definite period each day; atropine drops should also be inserted into the better eye once or twice a week, in order to compel the use of the inferior eye. An operation may be undertaken later for cosmetic reasons, but only after the essential cause has been dealt with. The condition in alternating strabismus is different; glasses alone will not suffice. In consequence of the alternate use the vision is often equal in the two eyes, and an operation is indicated earlier. In non-accommodative strabismus the deviation is the result, and not the cause, of the poor vision. Macular haemorrhages at birth may have made the vision so poor that there is no impulse to binocular fusion, and the eye is allowed to deviate. There may even be aversion to fusion, due supposedly to congenital absence of a fusion centre. In such cases glasses will do no good; an operation may have cosmetic advantages, without improving the vision.

422 Epidemiology of Trachoma

A. J. MACCALLAN (*Brit. Journ. of Ophthalmol.*, July, 1931, p. 369) gives an accepted classification of the four stages of trachoma which is of the greatest use clinically and statistically. A specific organism, though long sought, has not yet been conclusively demonstrated. The geographical distribution of the disease is divided into sections according to the prevalence, Egypt, the Levant, Morocco, Algeria, Tunisia, Palestine, Arabia, Persia, and Iraq heading the list. No race is exempt; the infectivity is dependent upon the source of the contagion, and is increased by superadded conjunctivitis with profuse discharge. Children are more susceptible than adults, and in them the disease is more dangerous. Dissemination by flies is not improbable, but the usual route taken by the infection is digital, by towels, handkerchiefs, and bed-clothing. A minimal dose of virus may produce a severe form of trachoma. Health, altitude, and humidity have no influence upon the incidence, and the temperature of the locality is only concerned in so far as in hotter weather flies and ophthalmia are more prevalent. Trachoma is more common under bad social conditions; the sexes are equally affected, and trauma is not a factor in its occurrence. The prophylaxis is fully discussed under the headings personal, familial, scholastic, military, national, and international.

423 The Post-cycloplegic Test

H. BEARD (*Arch. of Ophthalmol.*, June, 1931, p. 943) states that the post-cycloplegic test should definitely be a supplement to refraction when atropine or homatropine has been employed. The "full correction" with cycloplegia should be determined. In hypermetropia and high astigmatism this "full correction" will probably have to be reduced when ciliary tone returns. The static and dynamic corrections are now known, and the problem is what adjustment should be made for the return of ciliary tone. The following questions must be considered: [illegible] are present? Do any glasses already [illegible] the symptoms, and to what extent? Is the unaided distance vision adequate? Would glasses which "blur" at 20 feet be compatible with the patient's occupation? Where a sufficiently full correction to relieve asthenopia cannot be tolerated for constant wear, a second weaker pair may be ordered for distance. Generally there should be no alteration of the cylinder found in the static test. In myopia the ciliary tonus is rarely prominent and the correction should be full.

Obstetrics and Gynaecology

424 Bouilly's Operation for Prolapse

C. LENORMANT and P. DREYFUS (*Gynécol. et Obstét.*, July, 1931, p. 1) regard Bouilly's operation as the most suitable radical treatment of moderate and severe degrees of prolapse in young women. It consists in (1) a wide anterior colpectomy; (2) amputation of the cervix; and (3) posterior colpo-perineorrhaphy. The amputation of the cervix, besides curing hypertrophy or cervical metritis (one or other of which was present in fifty-seven of the writer's seventy-three cases), determines an involution of the corpus uteri, and leads to cicatricial fixation of the remnant of the cervix. For cases of prolapse without much descent of the uterus, and with a healthy cervix, colpo-perineorrhaphy is preferable, with ligamentopexy for retroversion; in the massive prolapses of old women, vaginal hysterectomy should be combined with a plastic operation. In the first stage of the Bouilly operation the present authors have never wounded the bladder; they admit, however, that in the second stage haemostasis of the cervico-vaginal arteries may cause considerable difficulty, and the pouch of Douglas is sometimes opened. Secondary haemorrhage occurred in six of the seventy-three cases, proving fatal in two; the total mortality was three.

425 Heart Disease and Pregnancy

C. YOUNG (*Canadian Med. Assoc. Journ.*, August, 1931, p. 154) briefly discusses functional cardiac disease in pregnant women, and divides organic disease of the heart into two groups—namely (1) rheumatic valvular disease, and (2) gross heart disease. The first group includes cases without cardiac enlargement or signs of heart failure; the condition is usually mitral stenosis and regurgitation, or aortic regurgitation, or combinations of both. The author quotes two series of cases of mitral stenosis, totalling 110, with no deaths; only two patients developed signs of heart failure during pregnancy. Aortic regurgitation is a little more serious. A series of 25 cases is recorded, with 3 deaths, 6 heart failures during pregnancy, and 3 seriously damaged hearts after labour. Young

recalls that Mackenzie used to advise that such cases should be allowed to proceed to term if there were a good response to effort, no Carrigan pulse, and no cardiac enlargement. The second group comprises such cases as valvular disease with definite gross cardiac enlargement, myocardial degenerations, congestive failure, and auricular fibrillation. In mitral stenosis with cardiac enlargement, but good response to effort and no history of previous failure, the author considers that the pregnancy might be allowed to proceed to term, but in all other cases in this group he recommends therapeutic abortion as the safest procedure if the patients are seen before the fourth month. The best method is probably the insertion of a tent or gauze packing in the cervix, and sometimes curetting next day, under morphine and scopolamine with light ether anaesthesia. After the fourth month, on account of the greater risk of haemorrhage and of incomplete emptying of the uterus, delay is advocated. The cardiac reserve should be built up by rest in bed. It is extremely dangerous to induce labour during heart failure, and especially so in the later months. At Queen Charlotte's Hospital, Caesarean section at the twenty-fourth week is advocated. The author prefers the induction of labour medically or by other means at the thirty-sixth week, with ether in the second stage, and the patient digitalized. The patient should be kept in bed for at least a month after labour. The infant mortality is high in these cases. The author concludes by observing that it is astonishing how many women with apparently severely diseased hearts come through repeated pregnancies with remarkably little additional damage.

426 Operative Treatment of Ovarian Tumours

V. B. GREEN-ARMYTAGE (*Journ. Obstet. and Gynaecol. of the British Empire*, Spring Number, 1931, p. 111) reports his experience during ten years in treating ovarian tumours in Calcutta. He remarks that it is still a common error in India to consider such tumours as being of little importance and malignancy, with the result that they are allowed to persist until they reach an enormous size. He concludes that the date of operation should not be hurried, but the patient should be kept in bed until the heart and kidneys are functioning normally. These patients are frequently constipated and infested with worms, and therefore santonin and gentle purgation should be the routine procedure on admission. With a view to inhibiting operative shock and strengthening the cardiac muscle, the author prescribes honey and a liberal diet. A cachectic condition is frequently present, which renders it difficult to gauge the vital resistance of the patient. Before the operation is begun, and from the first moment of the anaesthesia, intravenous injections are given of a 20 per cent. glucose solution at the rate of 1 drachm per minute. Gentle compression of the abdomen is made during the operation by a long roller towel, which is placed round the patient's waist immediately below the costal margin. This maintains the abdominal pressure, and obviates the filling up of the splanchnic vessels, consequent upon removal of the tumour. The author strongly commends this procedure, which also prevents any sudden movement of the heart downwards as the result of release of tension upon the diaphragm. In the case of very large tumours the pressure on the diaphragm may be so great as to cause cyanosis; in these circumstances open ether and oxygen are administered with the patient in a slightly prone position. Excellent results have also attended the employment of avertin anaesthesia.

427 Pregnancy Diagnosis Tests

L. BROUHA and H. HINGLAIS (*Gynécol. et Obstét.*, July, 1931, p. 43) discuss the technique of the Brouha-Hinglais-Simonnet test for the diagnosis of pregnancy, described first in 1928. Into infantile male mice, aged about four weeks, is injected subcutaneously the urine of a pregnant woman, and at the eighth to tenth day the animals are killed; if the pregnancy reaction is positive, the vesiculae seminales show a large increase in size and weight. In 401 tests of pregnancy one error only was made; a positive reaction has been obtained so early as the fifth or eighth day after a missed menstrual period. Death of the injected animal from toxicity of the urine is less common than in the females used in the Aschheim-Zondek test. An experienced observer can give a report on the urine as early as the sixth day. It is essential that the male mice should be chosen by age, and not by weight. The reaction becomes negative 4 to 8 days after parturition; in cases of intrauterine death of the foetus the reaction becomes negative when the placenta perishes, and not when the foetus dies. In ectopic gestation a positive reaction lasts as long as chorionic activity persists. In certain cases of hydatidiform mole the urine gives a reaction which is much more intense than in ordinary pregnancy.

428 While working on the Aschheim-Zondek reaction, and employing rats instead of mice, DHARMENDRA (*Indian Journ. Med. Research*, July, 1931, p. 239) noted the effects of injections of pregnancy urine on male rats. It was found that in immature animals the testicles hypertrophy and descend into the scrotum, and that the seminal vesicles, prostate, Cowper's glands, and penis hypertrophy. In older animals with descended testicles, the hypertrophy of these structures is marked; the effects on adult rats are, however, variable. In view of these findings a modification of the test, using male rats, is suggested, descent of the testicles in the injected animals being the sign of a positive reaction. This obviates killing the animals, and the necessity of obtaining animals of definitely known age.

429 Syphilitic Disease of the Corpus Uteri

P. CAFFIER (*Zentralbl. f. Gynäk.*, June 27th, 1931, p. 2018) alludes to the difficulties of distinguishing between syphilitic and tuberculous disease of the corpus uteri, and believes that the first of these conditions is sometimes diagnosed on insufficient evidence. He records a case in which he believes the differential diagnosis to be uncertain, syphilis being the more probable. In the myomatous uterus of an apparently healthy unmarried woman, aged 39, there was found a generalized interstitial infiltration, with round and epithelioid cells, together with numerous giant cells; caseation was absent. Doubt was cast on the histological diagnosis of tuberculosis by the absence of clinical or radiological signs of thoracic tubercle; on the other hand, the Wassermann reaction was positive, and there was enlargement of the liver and spleen.

430 Influenza and the Puerperium

H. THERICEL (*Thèse de Paris*, 1931, No. 484), who records sixty-two cases in patients aged from 17 to 45, states that in a high percentage of cases, which it is difficult to determine statistically, influenza has an injurious effect upon the female genital organs, causing disturbance of menstruation in the form of menorrhagia, metrorrhagia, or amenorrhoea. It may not only set up acute inflammation of the uterus and adnexa, but also activate chronic processes, especially malignant tumours. It appears to have a predilection for pregnant women, in whom it is liable to cause abortion in the early stage and premature labour later, except in the mildest attacks. Although the age of the mother and the number of previous pregnancies do not appear to have any effect, the stage of pregnancy is important, since the nearer pregnancy is to term, the more serious the disease is likely to be. Influenza does not have a bad effect upon delivery, which takes place with unusual rapidity. On the other hand, labour has a disastrous effect upon the disease, frequently giving rise to a rapidly fatal pneumonia. The effect on the children of the mothers attack is very bad, some perishing *in utero*, or during or immediately after delivery, while many of those who survive have a subnormal weight. The diagnosis between influenza and puerperal fever is very difficult, but the pulse rate is of considerable value, since it remains slow in influenza and becomes rapid in puerperal fever (Wallich's sign). The induction of abortion and Caesarean section are contraindicated.

Pathology

431 The Use of Gelatin for Liver-function Tests

R. Mancke (*Münch. med. Woch.*, August 21st, 1931, p. 1430) has devised a liver function test depending on the efficiency of the protein-metabolizing functions of the liver. Alterations in the de-aminizing powers of the liver affect the amounts of amino-acids excreted in the urine. Since the pure amino-acids are too expensive for routine clinical use, Mancke administers a flavoured solution of 50 grams of gelatin which contains 25 per cent. of the amino-acid glycocoll. The amount of urine excreted every four hours afterwards is measured, and the amount of amino-nitrogen is estimated in each specimen by Folin's method. Normally the maximum excretion occurs during the first four hours, and the amount rapidly diminishes in subsequent specimens. In simple jaundice the amount of amino-nitrogen excreted during the first four hours is much increased, and may be as much as four times the normal. In another group of cases of abnormal liver function examined (mainly cases of cirrhosis) the excretion was delayed, and larger amounts appeared in the second and third four-hourly specimens than in normal subjects; the total was, however, not increased.

432 Vaginal Secretion in Early Pregnancy

Hartman found that in pregnant apes, at the time when the first menstrual period after conception was to be expected, red cells appeared in the vaginal secretion. Red cells have also been demonstrated in the vaginal secretion of pregnant rats. Kulitzy (*Zentralbl. f. Gynäk.*, August 8th, 1931, p. 2430) has made a series of investigations on women in order to see if this can be used as a test in the early diagnosis of pregnancy. In 72 per cent. of pregnant, and 16 per cent. of normal non-pregnant women during the intermenstrual period, red cells were microscopically demonstrable in the vaginal secretion. The author therefore concludes that the test is only of service in suggesting the possibility of pregnancy or confirming other indications. The possible origin of the red cells in the vaginal secretion is discussed.

433 Restoration of the Circulation in Replanted Limbs

Referring to the experiments of Halstead and other workers on the replantation of severed limbs, and on the vascular sequels of ligaturing procedures, F. L. Reichert (*Bull. Johns Hopkins Hosp.*, August, 1931, p. 86) reports experimental studies which throw light on the inter-dependence of the vascular systems (arterial, venous, and lymphatic) in maintaining an adequate circulatory balance, and on the comparative value of ligaturing the artery and vein, either simultaneously or tying the veins later. After replantation, arterial regeneration was demonstrated on the second and third days, venous restoration on the fourth and fifth, and lymphatic re-appearance as early as the fourth day after the operation. Gangrene does not develop if the main vein is tied five or more days after replantation, whereas the artery alone cannot be safely occluded until the fourteenth day. The time interval for a safe arterial ligaturing can be diminished to seven days, when the artery and vein are simultaneously tied. Experience with war wounds has definitely indicated that in arterial ligaturing the incidence of gangrene may be diminished by the occlusion, at the same time, of the accompanying vein. The lymphatic system also was proved to be an important factor in maintaining an adequate afferent circulation.

434 Calcium and Phosphorus Metabolism in Nephritis

F. J. Ford (*Arch. Dis. in Child.*, August, 1931, p. 209) has investigated by "balance studies" the metabolism of calcium and phosphorus in renal disease, with special reference to their utilization, absorption, and excretion in nephritis. He finds that the urinary excretion of both is diminished, that of calcium more markedly. The amounts of the two elements thus excreted bear no relationship to their respective retentions in the body, nor to the volume of the urine passed, but the faecal output of both is increased in nephritis. The rise in the phosphorus excretion by the bowel is greater than that in the case of calcium, the normal CaO to P_2O_5 ratio being reduced almost to unity. The process of restoration of the normal route of excretion is extremely slow, and is delayed for some time after the onset of convalescence. The retention of calcium and phosphorus in nephritis, he adds, does not appear to be unusually high, and their absorption is adequate, though it varies more widely than in healthy persons.

435 Preservation of Blood-grouping Serums

L. Rosenthal (*Journ. Lab. and Clin. Med.*, August, 1931, p. 1123) points out that the contamination of haem-agglutinating serums by bacteria may be a source of error in blood-grouping tests, and that, where these tests are performed frequently, the maintenance of sterility in the serums is difficult. The addition of various disinfectants such as chloroform, phenol, and glycerin has proved unsatisfactory, owing to the formation of precipitates. Dyes, such as brilliant green and gentian-violet, protect the serums from bacterial contamination, and, moreover, by selecting dyes of different colours, mistakes due to erroneous labelling may be avoided. Rosenthal adds to each cubic centimetre of Group II serum 0.01 c.cm. of a 1 per cent. aqueous solution of neutral acriflavine, and 0.01 c.cm. of a 0.5 per cent. aqueous solution of basic fuchsine; to each cubic centimetre of Group III serum 0.02 c.cm. of a 1 per cent. aqueous solution of brilliant green. Thus the Group II serums are coloured red and the Group III green.

436 The Aschheim-Zondek Test

M. Watrin and H. Brabant (*C. R. Soc. de Biologie*, August 5th, 1931, p. 1418) claim to have been the first to doubt the hypophyseal origin of the substance causing the characteristic ovarian changes in the Aschheim-Zondek reaction. These doubts are based on both teleological and biological grounds, which are described in their present report. From an experimental study these investigators conclude that the substance present in the urine of pregnant females is of placental origin, and has an elective, necrotic action on the ovule and the granular layer of the ovarian follicles. This necrosis is either accompanied by intrafollicular and medullary haemorrhages, or determines a massive atresia of the follicles with hyperplasia of their internal thecae. Other substances (the urine of cancerous men, epiphyseal extract, emulsion of spermatozoids) and thyroid implants can also give rise to the Aschheim-Zondek reaction. Nevertheless, it is not improbable that the placental substance has a biological function to play, apart from arrest of follicular maturation during the last months of pregnancy, when the corpus luteum atrophies. Though this is only a hypothesis, the authors believe that it explains why only the urines of those mammals, as man and the primates, in which gestation is long, contain this substance, atresic for the ovarian follicles.

437 Cod-liver Oil in Powder Form

G. Mansfeld and Z. Horn (*Deut. med. Woch.*, August 21st, 1931, p. 1452) have tested a powdered form of cod-liver oil (jemalt) for both its growth-promoting and anti-rachitic effects. The powder contains 30 per cent. of dried cod-liver oil, and is said to have a pleasant taste. The growth experiments were carried out on young white rats kept in the dark on a rachitogenic diet. The rickets experiments were designed to test the therapeutic and prophylactic effects of the preparation, and were controlled chemically, radiologically, and histologically. The authors conclude that this powdered preparation of cod-liver oil retains its activity as far as vitamins A and D are concerned.

PREVENT WINTER INFECTIONS

By starting with prophylactic measures now and continuing them till the spring, susceptible patients may be effectively protected against the common winter infections—influenza and pneumonia, bronchitis and recurrent colds.

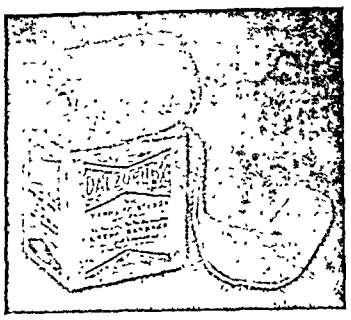
Adexolin Capsules offer a simple, economical and scientifically well-established means of conferring such protection. Each capsule contains the vitamin A content of three to four drachms of high-grade medicinal cod-liver oil and the amount of vitamin D normally found associated in cod-liver oil with that amount of vitamin A.

The anti-infective action of these vitamins has been demonstrated both by controlled laboratory investigations and a growing clinical experience, and two capsules daily would appear to give a considerable increase in the body resistance.

Vitamin A, the first line of defence, exercises its anti-infective action by preserving the integrity of epithelial tissues, vitamin D reinforces this action by maintaining the calcium and phosphorus content of the blood at an optimal level and enhancing its bactericidal power.

In cases of acute infection Adexolin brings down the temperature and pulse rate, promotes resistance, and hastens the resolution of the infective process. To achieve this end Adexolin must be given in large doses as indicated below.

ADEXOLIN CAPSULES



ADMINISTRATION At the onset of a cold or influenzal attack resulting from naso-pharyngeal infection, one Adexolin capsule, 4 or 5 times daily may be given. As a general tonic, one or two capsules a day are given, and this alone seems to raise considerably the resistance to infections. In the treatment of acute infective processes the maximum dose which is tolerated without causing nausea or sickness may be administered. This is usually one or more capsules every waking hour.

Boxes of 25 capsules ... ... 3/9 per box.
Boxes of 100 capsules ... ... 12/6 per box.

'DALZOFLEX'
Regd.

The Perfect Varicose Ulcer Dressing.

There is no better—astounding results.

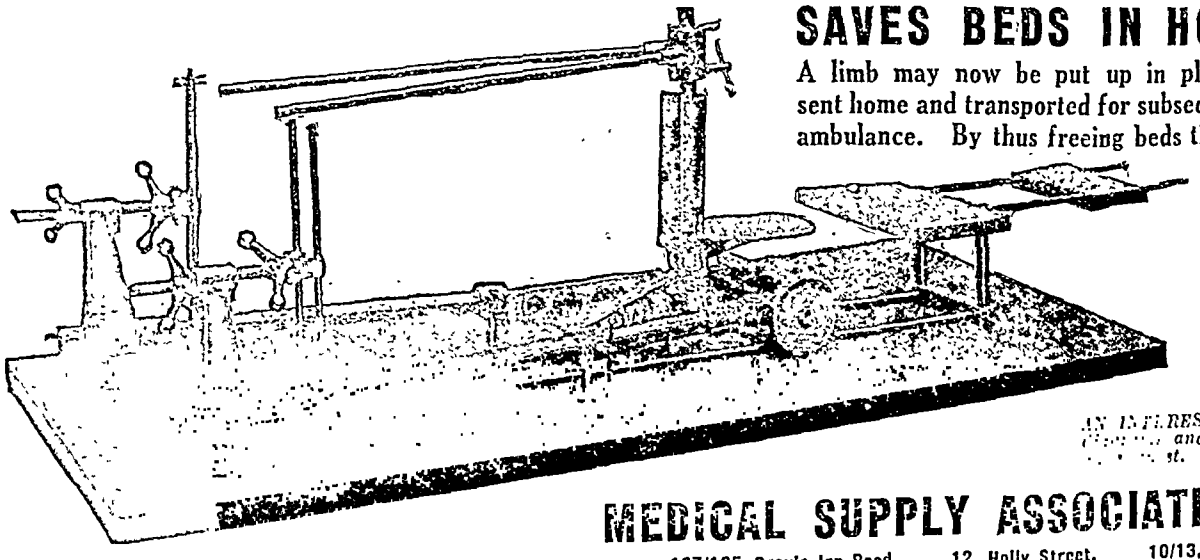
Manufactured by

A. DE ST. DALMAS & Co. Ltd.,
Est. 1823. **LEICESTER.**

The 'LEICESTER'
Perfect Plaster of Paris Bandages.

(1) No loose powder.
(2) Sets quickly.
(3) Once set can be washed.
(4) Exceedingly light cases, only half the weight of the loose Powder Bandage.
(5) Cases can be cut open and used several times by lacing up.

B. & C. Standard.
100% Efficiency.



An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

1. It is individually fitted to suit the case for young, mid-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sound from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS
arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deaf ness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting

MEDICAL REPORTS
Commended by all leading medical journals.—Mr. R. H. Dent will be happy to send full particulars and reprints on request, and also arrange demonstrations.

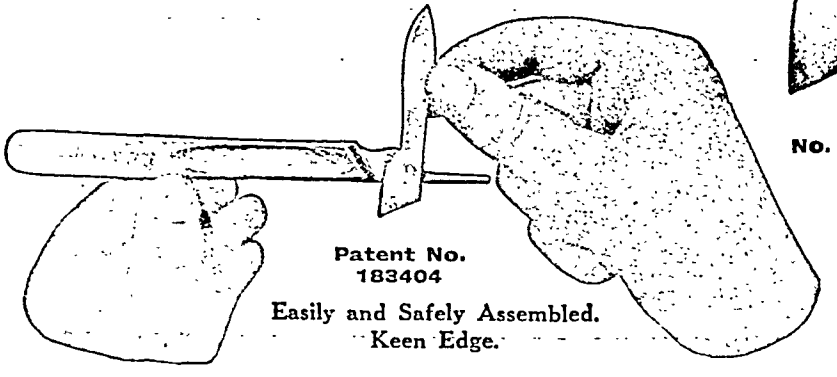
ESTABLISHED 1793



IN all cases where woollen underwear is not only needful but absolutely vital, Wolsey is the wisest suggestion to make. For Wolsey underwear is made of purest wool and offers all the blessings of health and comfort that only pure wool provides. It is soft and warm and, above all, hygienically right. Scientific investigations* have proved that garments made of wool do more than any other to prevent the deposition of moisture on the skin; retain warmth better than any other material, and thus allow the most equable body temperature possible.

"CEREBAN" ADHESIVE AND SELF-SUPPORTING Bandage

SPECIALLY PREPARED FOR THE TREATMENT OF SPRAINS DISLOCATIONS, CONTUSIONS, SWELLINGS, VARICOSE VEINS, VARICOSE ULCERS, etc., etc.

"CEREBAN" is a resin-impregnated Bandage, spread on extensible material, free from rubber and possessing elastic properties. When carefully applied it gives substantial and firm support Porous, adhesive, and non-irritating. Experience has proved that "Cereban" Bandages are particularly suitable as a protective after-care treatment in the healing of Varicose Ulcers, etc.

"Cereban" offer many advantages over the old-fashioned Elastic Stockings or Plain Crepe Bandages ... leading to speedier recovery.

ESTABLISHES REGULAR EVACUATION

It is admitted that the large majority of patients suffer from the direct or indirect effects of constipation. It is often difficult to educate them to combat these evils. Some are ignorant, others apathetic, while many of them dread the griping pains and weakness occasioned by the ordinary laxatives. Sal Hepatica is pleasant to take and both prompt and painless in action. It maintains the biliary secretion in a healthy fluid state, and ensures freedom from congestion and from that subacute inflammation of the gall bladder which is at present so common, especially amongst sedentary workers. Sal Hepatica does not create a condition of tolerance. It is, therefore, the laxative of choice in chronic constipation.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to Bristol-Myers Company, 112, Cheapside, London, E.C.2.

Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Sal Hepatica the proved medicinal, saline laxative and cholagogue.

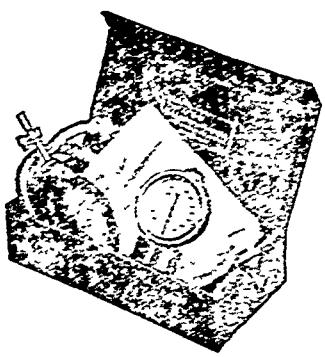
Is it fair to your best friend to make him your Executor? The duties are onerous, and usually thankless; the responsibilities are great and the penalties for neglect are severe. Moreover, he may die, and the expense of appointing his successor is considerable. On the other hand, if you appoint the Westminster Bank instead, the fees (which are paid out of your estate) will probably be only a fraction of the legacy which you would have left to a private trustee.



Ask for the 'Executor and Trustee' booklet at any local branch, or call at

WESTMINSTER BANK

Accurate Arterial Pressure Readings

For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs. Although one of the most delicate and accurate instruments of the medical man's equipment, the portable type as illustrated can be carried without fear of breakage. There is no glass tubing to break, no mercury to spill, and the readings can be verified at a glance by comparing the relation of the hand to the immovable zero.

Care should be taken to avoid imitations. Look for the trade mark "TYCOS" engraved on the dial of every genuine instrument.

Obtainable from all reputable Instrument Dealers.

Greater Comfort for your Patients.

"The Rose Corset-Belt"

which has set a new standard and proved so effectual in all abdominal cases where support is required. The X-rays have shown the actual uplift.

Each Corset-Belt is cut and fitted to individual requirements, and the patient is kept under observation until every satisfaction is given to both patient and doctor.

I have also invented an improved Colotomy Belt for both male and female patients.

My work is recommended by eminent members of the medical profession, and the following hospitals: St. Bartholomew's Hospital, Metropolitan, Charing Cross, Middlesex, London Temperance.

MADAME ROSE, 97, Mortimer St., Regent St., W.1. LANGHAM 1575.

Trade "HEPATAGEN" Mark

(MIST. HEPATICA CONC. HEWLETT.)

Composition.—Ext. Cascarae, Ext. Rhei, Jalapin, Podophyllin, Cocainae Hydrochlor., 1-20th gr. in each fluid drachm.
This preparation does NOT come under the Dangerous Drugs Act.

THIS excellent compound has now become a popular remedy in that class of cases spoken of as Chronic Biliousness, in Catarrhal Jaundice, and in the Jaundice of simple Hepatic Torpor. In passive or habitual Congestion of the Liver, so frequently met with, it has been used with marked benefit.

In the treatment of acute or temporary constipation, frequently met with in the convalescence from acute disease, and in pregnancy or in the constipation due to sedentary habits, the mixture can be prescribed with wonderful effect.

The Dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient, and is not accompanied by griping or tenesmus.

Packed for Dispensing only in 5-oz.; 10-oz.; 22-oz.; 40-oz.; and 90-oz. Bottles. Price in England, 12/6 per pound.
This preparation is also supplied "sine Cocaina," the dose and price remaining the same.

STANIFORM
Regd. BRAND. Trade Mark.
METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is contra-indicated.

LINIMENT
Remarkably *effective* in treatment of Rheumatoid Arthritis.

LOTION
A panacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are two recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"After using 'Staniform' Ointment in cases of Impetigo and other septic conditions of the skin, I was much impressed by the rapid response to treatment. Also herpes on the lip quickly disappeared after application of 'Staniform' Ointment."

"Festering wound on left heel—when first seen was about the size of a shilling, with a good deal of pus. Foot much swollen—dressed with 'Staniform' Ointment—healed splendidly in four days."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments.

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative proj[illegible] usefulness of Tin in staphylococcic infect[illegible]d properties of Iodine, Staniform is indicated [illegible] inducing an immediate soothing effect with rapid healing.

A modern country house, 12 miles from Marble Arch, in beautiful and secluded grounds.

Fees from 10 guineas per week.

Voluntary Patients received for treatment.

Special provision for "Temporary" patients under the new Mental Treatment Act.

DOUGLAS MACAULAY, M.D., D.P.M.

TREATMENT of EARLY MENTAL CONDITIONS

Medical Men having cases presenting any of those numerous states of ill health and disability now more generally recognised as often primarily due to minor psychoses and neuroses, and in need of investigation with view to decide on the treatment best likely to promote recovery and to prevent further mental deterioration, are invited to apply for particulars below, where for some years past a number of such cases, in both sexes, have been successfully dealt with.

The number in residence at any one time being strictly limited, close individual attention can be given, whilst the patient is provided with a comfortable home life in pleasant surroundings, with suitable occupation for leisure hours.

Certified cases and those definitely certifiable are not accepted.

RESIDENT PHYSICIAN, Elmsleigh, Bassett, Southampton

BARNWOOD HOUSE,

GLOUCESTER.

A REGISTERED HOSPITAL for the CARE and TREATMENT of LADIES and GENTLEMEN suffering from NERVOUS and MENTAL DISORDERS. Within two miles of the G.W. Railway and L. M. & S. Railway Stations at Gloucester, the Hospital is easily accessible by rail from London and all parts of the United Kingdom. It is beautifully situated at the foot of the Cotswold Hills, and stands in its own grounds of over 280 acres. Voluntary boarders of both sexes are also received for treatment.

Special accommodation for Lady Voluntary Boarders is also provided at the MANOR HOUSE, which has its own private grounds and is entirely separate from the main Hospital.

For particulars as to terms, etc., apply to—
ARTHUR TOWNSEND, M.D., Medical Supt.
Telephone: No. 7 Barnwood.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary *patients*, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths; the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

HAYDOCK LODGE,

NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

TYKEFORD ABBEY, NEWPORT PAGNELL,

BUCKS.

FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

An Approved Nursing Home for reception of Female Cases under the Mental Treatment Act.

The Home is a Mansion of Historical interest, standing in 9 acres of garden and grounds, and is situated 14 miles from Northampton, and 12 miles from Bedford on the main London to Northampton Road, fifty miles from London. Both sexes are accommodated. Psycho-Therapeutic Treatment is used extensively in suitable cases. Radiant Heat, X-Ray, and Ultra-violet Light. Diathermy and Foam Baths. Billiards, tennis, etc. Fees from five gns. per week.

Apply, Dr. D. E. M. DOUGLAS-MORRIS. *Telephone*: Newport, Pagnell 121.

COURT HALL, KENTON, EXETER,

SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Telephone: Starcross 19.
Limited to eight patients.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: Teignmouth 289.

RUTHIN CASTLE, NORTH WALES

REDUCTION OF FEES

In view of the present economic position, the inclusive fees at Ruthin Castle, formerly from 17 guineas a week, have been reduced to from 15 guineas a week, beginning on October 19th, 1931.

The fees include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary x-ray examinations, and electrocardiograph readings, all treatment that may be prescribed, such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, nursing, medicines or vaccines, board and lodging

The only extra charge is that for a complete alimentary x-ray examination, or for x-ray therapy

Many people who would go abroad for health will not do so this winter All the usual forms of treatment are given at Ruthin Castle The climate is mild The annual rainfall is 30 5 inches, that is, less than the average for England. There is central heating throughout Should the accommodation in the Castle not prove sufficient, comfortable rooms can be obtained near by for those undergoing treatment

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the *X*-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

The County Council of Middlesex.

ASSISTANT MEDICAL OFFICER

The County Council invites applications for the post of Assistant Medical Officer in the Public Health and School Medical Department. Applicants must be duly qualified registered Medical Practitioners, and should have had special experience of practical Midwifery and Ante-Natal work.

The duties of the post are the medical inspection of school children, the supervision of treatment of minor ailments, the carrying out of work under the maternity and child welfare scheme, and such other duties as may be required by the Council. The Officer appointed must devote his whole time to the duties of the post, will act under the supervision and control of the County Medical Officer of Health, and must reside in such district as may be required by the County Council.

Salary at the rate of £600 per annum, rising after two years' service by yearly increments of £30 to £750. Reasonable travelling expenses allowed.

The successful candidate will be required to contribute to the County Council's Superannuation Fund, and to pass such medical examination as the County Council may direct.

The appointment will be during the pleasure of the Council, and subject to one month's notice on either side.

Applications, stating (1) age, (2) qualifications, and (3) previous experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than November 14th. No special application forms are provided. Envelopes must be endorsed "Assistant Medical Officer."

Canvassing, directly or indirectly, will be a disqualification.

ERNEST SWART,
Clerk of the County Council.

Middlesex Guildhall, Westminster, S.W.1.
October 22nd, 1931.

County Borough of Dewsbury.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER

The Dewsbury Corporation invite applications from duly qualified and registered Medical Practitioners holding the Diploma in Public Health for the position of Medical Officer of Health and School Medical Officer at a commencing salary of £900 per annum, subject to a temporary reduction of 7½ per cent. until October 31st, 1932, when the question of the continuation of the reduction will be reviewed.

The gentleman appointed will be required to devote the whole of his time to the duties of the office, to reside in the Borough, and will not be allowed to engage in private practice. All emoluments or fees which may be payable to or received by him must be paid over to the Corporation.

The appointment will be made in accordance with, and subject to the Public Health Officers Act, 1921, and the Sanitary Officers Order, 1926.

Canvassing, either directly or indirectly, is prohibited. Applicants may, if they desire, forward 15 copies of their application and testimonials for the use of the members of the Committee.

Applications, with copies of not more than *three recent testimonials attached to be sent to* me endorsed "Medical Officer of Health," not later than November 12th.

TOM HALL HOLLAND BOOTH,
Town Clerk.
Dewsbury.
November 2nd, 1931.

County Borough of Huddersfield.

ASSISTANT SCHOOL MEDICAL OFFICER

Applications are invited from registered Medical Practitioners for the post of Assistant School Medical Officer.

The successful candidate will be required to devote the whole of his or her time to the duties of the office, and whilst these consist mainly of work in the School Medical Department they may also include work in any section of the Public Health Service. Experience in the diagnosis and treatment of Diseases in Children is essential.

The salary offered is according to scale £500 increasing by £25 per annum to £700, and the commencing salary will be based on the candidate's previous experience in the School Medical Service. It will be subject to a temporary cut which is in operation for one year on the salaries of all the corporation officials. On £500 the cut will amount to £17 10s.

Applications, stating age, and giving full particulars regarding training, qualifications and appointments held since qualification, should be forwarded to the undersigned, along with copies of two recent testimonials, so as to reach him not later than Thursday, Nov. 12th.

JOHN M. GIBSON, B.A., M.D., D.P.H.,
Chief School Medical Officer.

Corporation of Kingston-upon-Hull, and the Hull and Goole Port Sanitary Authority

SENIOR ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation of Kingston upon Hull and the Hull and Goole Port Sanitary Authority invite applications for the appointment of a male Senior Assistant Medical Officer of Health at a salary of £800 per annum, rising, subject to satisfactory service, by annual increments of £25 to £1,000 per annum.

Applicants must be registered medical practitioners under 40 years of age, and must hold a registered degree or diploma in Public Health or State Medicine.

The person appointed will be responsible to the Medical Officer of Health for the detailed administration of the Port Sanitary Service, Infectious Diseases Department, and to a large extent for the central administration of two Public Assistance Hospitals, and may be called upon to do work in any other departments of the Public Health Service, in accordance with the Corporation's scheme for the interchange of medical staff.

Experience in Port Sanitary Work and Infectious Diseases is essential.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the successful candidate passing a medical examination by a doctor appointed by the Corporation.

Forms of application and further particulars of the duties and conditions of service can be obtained from the Medical Officer of Health, Guildhall, Hull.

Applications, endorsed "Senior Assistant Medical Officer of Health," together with copies of three recent testimonials, must reach the Medical Officer of Health not later than November 14th.

Guildhall, Hull. J. B. HOWARD ROBERTS,
October, 1931. Town Clerk.

City and County of Kingston-upon-Hull

CITY HOSPITAL, COTTINGHAM

RESIDENT MEDICAL OFFICER

The Corporation invite applications for the appointment of a male (or female) Resident Medical Officer to undertake under the Medical Superintendent the medical work of the Infectious Diseases Hospital. Commencing salary £330 rising subject to satisfactory service, by annual increments of £25 to a maximum of £450 per annum, together with board, laundry, and residence.

Applicants must be not more than 40 years of age and must possess general clinical experience. The possession of experience in a fever Hospital will be regarded as an additional qualification.

The successful candidate will be required to reside at the City Hospital, and to devote the whole of his time to the service of the Corporation. He will be required to pass a medical examination, and to contribute to the Corporation's Superannuation Fund.

Applications, on forms to be obtained from the undersigned, with copies of not more than three recent testimonials, and endorsed "Resident Medical Officer, City Hospital," should be forwarded not later than noon on Saturday, November 14th.

Health Department, N. GEBBIE,
Guildhall, Medical Officer of Health.
Hull, October, 1931.

County Council of the West Riding of Yorkshire.

APPOINTMENT OF CONSULTANT TUBERCULOSIS OFFICERS.

The County Council of the West Riding of Yorkshire invite applications for the appointment of Three Consultant Tuberculosis Officers.

The applicants must be highly skilled in the knowledge and treatment of tuberculosis. They will be responsible for all forms of treatment carried out at the Dispensaries within the areas allotted to them, and will be available for consultation with the medical practitioners within the areas.

Salary £750 per annum, rising by biennial increments of £50 to £1,100. For the present the above salary is subject to a reduction of 8½ per cent.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Further particulars and form of application may be obtained from the undersigned, by whom all applications together with copies of not more than three recent testimonials must be received no later than November 16th.

County Hall, J. CHARLES McGRATH,
Wakefield. Clerk of the County Council.
October, 1931.

Borough of Ilford.

APPOINTMENT OF WOMAN ASSISTANT MEDICAL OFFICER OF HEALTH

Applications are invited from legally qualified Medical Women for the office of Assistant Medical Officer of Health, for duties in connection with Maternity and Child Welfare work, School Medical Inspection and General Public Health work. Candidates must possess the Diploma of Public Health or similar qualification and have had post-graduate experience in Maternity work and Children's diseases.

The commencing salary of the officer will be £400 per annum, rising on report of satisfactory service, by annual increments of £25 per annum to £500 per annum (no terms), and with free board and residence at the Corporation's Isolation Hospital.

The person appointed will be required to devote whole time to the duties of the office, to reside at the Isolation Hospital, and to enter into a contract for the due performance and fulfilment of all the duties and conditions governing the appointment.

The appointment is subject to satisfactory medical examination, to the Superannuation Act, 1922, and to the Local Government and Other Officers' Superannuation Act, 1922.

Candidates must not be more than 45 years of age.

Applications, which must be made on forms obtained by personal application from the undersigned, accompanied by copies of three recent testimonials (which will not be returned), endorsed "Woman Assistant Medical Officer of Health," must be delivered at my office at the Town Hall, Ilford, not later than Thursday, November 12th.

Canvassing, directly or indirectly, will be prohibited and will disqualify.

By Order,
Town Hall, ADAM PARTINGTON,
Ilford. Town Clerk.
October 29th, 1931.

Lancashire County Council.

APPOINTMENT OF ASSISTANT MEDICAL SUPERINTENDENT FOR WEIGHTINGTON HOSPITAL, PARBOLD, LANCS.

APPOINTMENTS.—Contd.

County Mental Hospital,
LANCASTER.

Applications are invited for the post of ASSISTANT MEDICAL OFFICER. Candidates must be single and under 35 years of age. Commencing salary £500, rising by annual increments of £25 to £600, with further increase on promotion, subject to a deduction of 3 per cent. under the Asylum Officers Superannuation Act. There are no emoluments. The selected candidate will be required to live in the Hospital, and he will be provided with board, lodging, etc., for which a charge of £150 a year is made.
The possession of a Diploma in Psychological Medicine will entitle the Officer to an additional £50 per annum.
Applications, giving full particulars, with testimonials (copies only), should be forwarded to the Medical Superintendent before Nov. 23rd.

The Mount Vernon Hospital,
NORTHWOOD, MIDDLESEX.
(The National Centre for the Study and Treatment of Cancer)

There is a vacancy for a RESIDENT MEDICAL OFFICER.
Candidates must be fully qualified and registered. Salary at the rate of £250 per annum, with board, lodging, etc.
Applications, with copies of three testimonials, to be sent to the undersigned not later than November 28th.
W. J. MORTON, Secretary.
Offices: 32, Fitzroy Square, W.1.

St. Thomas's Hospital Medical SCHOOL.
VACANCY.

PATHOLOGIST to the Medical and Surgical Units. Salary £400 per annum.
Applications, accompanied by full Academic record and two testimonials, to be rendered to the Dean's Office by November 20th.

Aberdeen Royal Mental Hospital.

The office of JUNIOR ASSISTANT PHYSICIAN (male) in Aberdeen Royal Mental Hospital is vacant, and applications for it are invited.
Salary will commence at £300 per annum, with board, lodging, and laundry.
Applications, stating age and qualifications, with copies of testimonials, should be sent to the Physician Superintendent.

County of London.

The LONDON COUNTY COUNCIL invites applications for appointment as FIRST ASSISTANT MEDICAL OFFICER (man or woman) at the MAUDSLEY HOSPITAL, Denmark Hill, S.E.5 (for treatment of incipient mental disorder). Candidates must be not more than 40 years of age (unless already in the Council's Mental Hospital Service), must be registered to practise both in medicine and surgery in England, and must have held a residential position in a General Hospital for six months or have had comparable general experience. Appointment pensionable under the Asylums Officers Superannuation Act, 1909. Salary £750 a year, rising to £850 a year. No emoluments. Charges made for board, lodging, etc. (at present £2 9s. weekly), if required to be resident. In the case of a woman, marriage terminates contract of service. Application form giving full particulars obtainable from Chief Officer (Ref. B) L.C.C. Mental Hospitals Department, Artillery House, Artillery Row, S.W.1. Applications must be received by November 28th. Canvassing disqualifies.
MONTAGU H. COX,
Clerk of the London County Council.

County of London.

The LONDON COUNTY COUNCIL invites applications for appointment as ASSISTANT MEDICAL OFFICER (male) in the Mental Hospital Service. Candidates must be under 35 years of age. They must be registered to practise both in medicine and surgery in England, must be of at least one year's professional standing, and must have held a residential position in a General Hospital for six months or have had comparable general experience. Salary £475 a year, rising to £550 a year (additional allowance of £50 a year to holders of D.P.M.). No emoluments. Charge for board, lodging, etc. (at present £2 9s. a week) if required to be resident. Pensionable under Asylums Officers Superannuation Act 1909. Application form, giving full particulars, obtainable from Chief Officer (Ref. B), L.C.C. Mental Hospitals Department, Artillery House, Artillery Row, S.W.1. *Applications* must be received by November 28th. Canvassing disqualifies.
MONTAGU H. COX,
Clerk of the London County Council.

Borough of Mansfield.
TEMPORARY ASSISTANT (FEMALE) MEDICAL OFFICER OF HEALTH.

Applications are invited for the appointment of Temporary Assistant (Female) Medical Officer of Health for the Borough of Mansfield, for a period of twelve months, at a salary of £500 per annum.
The duties will include the Medical Inspection of school children, work in connection with Maternity and Child Welfare Centres, Antenatal Clinics, etc.
Candidates must be registered Medical Practitioners, hold a Diploma of Public Health, and have had at least three years' experience of post-graduate work.
The successful candidate will be required to devote the whole of her time to the duties of the office and to reside in the Borough.
The appointment will be subject to the approval of the Ministry of Health.
Applications, which must be made on forms obtainable from the undersigned, accompanied by copies of three recent testimonials, endorsed "Temporary Assistant Medical Officer of Health," must be received at my office not later than November 21st.
Town Clerk's Office, Mansfield. A. C. SHEPHERD, Town Clerk.

BOVRIL MEDICAL AGENCY, Ltd.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. Telephone: TEMPLE BAR 1616 (3 Lines).

Under the personal directorship of Dr. J. FIELD HALL and J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges. No charge is made to Principals for the introduction of Locum Tenens or Assistants.

1. LONDON, S.W.—Good middle-class PRACTICE, offering considerable scope, and producing for the past 12 months over £670, including panel of nearly 400. Fees from 2/6. Midwifery 3 gns. (about 30 cases yearly). Suitable house, with dining room, consulting room, and dispensary, 5 bedrooms, sitting room, etc. Price for leasehold (94 years to run) £1,200, part on mortgage. Premium £1,050.
2. MIDLANDS.—PARTNERSHIP.—A one-third share is offered in a very sound middle and working-class Practice, held by the senior partner for 35 years. Average gross cash receipts for the past three years nearly £3,000. Panel of over 1,600. Fees 3/6 to 21/-. Midwifery from 3 gns. (about 60 cases). Suitable house available on rental, with 2 reception, 3 bedrooms, etc. Small garden. Garage. Sport of all kinds, and very good schools within reach. Prem. 2 years' pur.
3. NORTH OF ENGLAND.—FAVOURITE COAST TOWN.—Old-established middle and upper-class non-panel PRACTICE, averaging for the past three years nearly £5,000. Fees from 5/- to 21/-. Very suitable for two friends in partnership, one holding the F.R.C.S., as there is excellent surgical scope. Two good houses available, with ample accommodation, either on rental, or by purchase.
4. MID-WALES.—Agricultural District.—Mixed-class PRACTICE, producing about £880 p.a., including small panel of 130. Fees 3/6 to 21/-. Small house, with 2 reception, 3 bedrooms, etc. Price £550. Fishing, shooting, and other sport. Premium 1 year's purchase.
5. LONDON, E.C. (nr. Holborn Circus).—Old-established mainly working-class PRACTICE, producing about £700 p.a., including recently started panel of 360. Fees from 2/-. No midwifery. Six-roomed house can be rented on lease at £95 p.a. Good scope for increase. Premium £1,000, or near offer.
6. WEST OF ENGLAND.—Old-established general PRACTICE, situated in exceptionally nice neighbourhood, with good sporting and social facilities. Income averages about £1,000 p.a., with small panel of 400. Fees from 3/6 to 1½ gns. Particularly good house, with beautiful garden, and containing 2 reception, 7 bedrooms, etc. Price for freehold £2,000, part on mortgage. Excellent surgical prospects. Premium 1½ years' purchase.
7. WOMAN DOCTOR'S PRACTICE.—YORKS.—LARGE TOWN.—Established eight years, easily worked, and producing nearly £700 p.a. Panel of 500. Fees 5/- to 7/6. Midwifery 3 to 5 gns. Compact house, with 2 sitting, 2 bedrooms, 4 attics, etc. Garden. Garage. Rent on lease £42 10s. p.a. Prem. 1½ years' purchase, or near offer.
8. SOUTH OF ENGLAND.—Favourite Coast Town.—NURSING HOME, with small private Practice combined, the latter offering very good scope for development. Total receipts last year about £600. Very nice detached house, with excellent accommodation, very well appointed. Price for leasehold (87 years to run) £1,250, to include all furniture, fittings, and fixtures, drugs, and instruments, etc.
9. MIDLANDS.—COUNTY TOWN.—PARTNERSHIP.—A one-fourth share is offered in an exceptionally sound good mixed-class Practice, averaging over £6,000 p.a., including panel of 3400. Lowest fee 4/-. Very little midwifery. If single, purchaser can live in comfortable rooms; otherwise choice of houses for sale or on rental. Premium 2 years' purchase.
10. NORTH OF ENGLAND.—GOOD TOWN.—A one-third share is offered in a very sound Practice, averaging about £5,000 p.a. Ingoing Partner must be well qualified and not over 35, and interested in medicine. Suitable house available. Premium 2 years' purchase.
11. CHESHIRE.—NEAR COAST.—Old-established middle and working-class PRACTICE, averaging for the past three years over £1,300. Panel of 550. Fees from 3/6. Good house, with 3 reception, 7 bedrooms, etc. Price for freehold £1,200, part on mortgage. Premium 2 years' purchase.
12. WITHIN TEN MILES OF LONDON.—PARTNERSHIP.—The third share of an old-established good middle and working-class Practice is for disposal, offering excellent future prospects. Cash receipts last year amounted to nearly £2,700, including panel of nearly 1,500. Suitable house available at moderate price. Premium 2 years' pur.
13. WITHIN FOUR MILES OF THE BANK.—Old-established working-class PRACTICE, producing for the last 12 months £2,500, including panel of over 2,800. Appts. worth about £160. Visits from 2/6. Low expenses. Suitable house can be rented or bought. Surgery premises on rental. Premium £4,000 cash.
14. NORTH-WEST COAST.—SURGICAL PARTNERSHIP.—In a popular residential seaside resort the half share of middle and upper-class Practice is offered to a suitable gentleman possessing the F.R.C.S., as the retiring partner does the surgical work, the remaining partner the medical side. Receipts average nearly £5,000 p.a. Very good modern house, recently built, with ample accommodation, good garden, tennis court, etc. Rent on lease £240, or can be purchased. Premium 2 years' purchase.
15. LONDON, S.E.—Well-established mixed-class PRACTICE, averaging for past three years £3,885. Panel of 3,900, and appt. worth £200 p.a. Fees from 2/-. Mid. 30/- to 2 gns. Suitable house, in very good repair, with 2 reception, 6 bedrooms, ample professional accommodation; garage for 2 cars. Good garden. Rent on lease £90 p.a. Premium £7,500. £5,000 down and balance by arrangement.
16. PARTNERSHIP.—In a most desirable outlying residential suburb of London, a suitable partner (experienced, not over 30 years of age and married) can acquire a share producing (to commence with) about £1,200 p.a., in an old-established good mixed-class Practice averaging just over £10,000 p.a. Very good house, with ample accommodation. Rent £150 p.a. Premium 2 years' purchase cash.
17. MANCHESTER.—Good mixed-class PRACTICE, averaging over £1,200 p.a., but capable of much increase. Vendor having neglected work owing to ill-health. Panel of about 550. Fees 3/6 to 7/6. House, with 2 reception, 5 bedrooms, etc. Garden. Garage. Price £2,700. Premium 1½ years' purchase, payable by arrangement.
18. SOUTH AFRICA.—Within 100 miles of East London.—Increasing PRACTICE, in very pretty Township near sea coast, producing last financial year £1,066. Practically all fees cash. Climate excellent. No night work and little or no visiting. Living cheap. Bungalow residence in 3/4 acre of productive garden. Price £750, £400 on mortgage, or premium for quick sale £1,100 for Practice and house. Sport of all kinds.
19. KENT.—NURSING HOME, and small private Practice combined (the latter offering excellent scope if desired as it has not been developed), situated in very pretty district within 15 miles of London. Total receipts last year £1,100. Beautiful house (11 bedrooms, etc.) standing in 2½ acres of garden, tennis lawn, etc. Price for freehold and goodwill £2,100.
20. BORDERS OF BERKS AND HANTS.—In a delightful sporting and agricultural district, within reach of market town, an old-established mixed-class PRACTICE averaging about £850 p.a., including panel over 400. Visits 5/- to 10/6, medicine extra. House containing 3 sitting, 7 bedrooms, bathroom, etc. Large garden. Garage. Rent £50 p.a. on lease. Premium £1,100.
21. DEVON.—PARTNERSHIP.—Half share of very old-established unopposed Country Practice, offering scope, and situated in pretty village within reach of large town. Cash receipts last year £2,220, including appts. and panel of 880. Visits 3/6 to 21/-, medicine extra. House contains 2 reception, 4 bedrooms, bathroom, etc. Garden. Garage. Rent £30 p.a. Premium £2,000. Hunting, shooting, fishing, etc.
22. MIDLANDS.—COUNTY TOWN.—PARTNERSHIP.—A one-third share (with increase to one-half later) is for disposal in a particularly sound well-established mixed-class Practice, owing to the retirement of the senior Partner. Gross cash receipts average £4,379 p.a. (last year £4,437). Panel of 1,344. Consultations 3/6 upwards. Visits 5/- to 21/-. Very suitable house, with 3 reception, 6 to 7 bedrooms, etc. Garden. Garage. Rent on lease £100 p.a. First-rate schools and sport. Premium 2 years' purchase.
23. NORTH DEVON & CORNWALL BORDERS.—Very old-established unopposed Country PRACTICE, in beautiful district near coast. Cash receipts average just over £1,100 p.a., including appt. and panel of 330.—Suitable house available. Premium £1,600, to include drugs, etc. Hunting, golf, fishing, etc.
24. SOUTH OF ENGLAND.—Pleasant Town near Coast.—Very old-established middle and upper-class PRACTICE. Cash receipts average nearly £1,750 p.a., including panel of 500. Visits 3/6 to 21/-. Very little midwifery. House, including consulting room, waiting room, and dispensary, in well-situated part of town. Price, freehold, £1,500.
25. CATHEDRAL CITY (NORTH).—PARTNERSHIP.—Third Partner required in very old-established lucrative and increasing middle and working-class Practice. Cash receipts for past three years average £4,544 p.a. (last year £4,911), including panel about 4,000. A fifth share is for disposal, with increase to a third later. Suitable accommodation available. Premium 2 years' purchase.
26. NORTH MIDLANDS.—WITHIN 3 MILES OF FAVOURITE TOWN.—Old-established good middle-class PRACTICE, offering large scope. Cash receipts for last 12 months £1,332, including panel of over 1,000. Fees from 3/6. Mid. from 2 gns. Exceptionally nice house, in about 4 acres of ground, with tennis lawn, fruit and vegetable gardens, etc., containing 3 reception, 6 bedrooms, etc. Freehold for sale. Premium 1½ years' purchase.
27. MANCHESTER.—Semi-residential Suburb.—Very old-established non-dispensing mainly middle-class PRACTICE, averaging £2,500 p.a., including small selected panel of 440, which latter is capable of extension. Visits 5/- upwards. Only about 20 cases of Midwifery from 5 gns. Well-situated house, with good accommodation. Price (freehold) £1,600. Premium £3,750.

'Pituitrin' and Theelin

IN MALIGNANT DISEASE

THE preliminary report on the use of 'Pituitrin' and Theelin for the treatment of cancer published in the *British Medical Journal*, October 31, 1931, has aroused considerable interest. The results appear to be such as to justify further trial of this treatment, which is based on a definite theory of the rôle of the pituitary gland in malignant disease.

The preparations used in this important work were 'Pituitrin' and Theelin—two Parke, Davis & Co. products.

'PITUITRIN'

'Pituitrin,' the original preparation of posterior pituitary introduced by Parke, Davis & Co. in 1908, is still the leading preparation of its class. It is unsurpassed for reliability of action, uniformity of activity, purity, and stability. It is assayed by both the pressor and the oxytocic method.

Supplied in boxes of 6 or 12 ampoules of 0.5 c.c. or 1 c.c.

THEELIN

Theelin is the crystalline ovarian hormone, first isolated by Dr. E. A. Doisy, Professor of Biochemistry at the St. Louis University. It is manufactured by Parke, Davis & Co. and is tested and approved by the Biochemical Laboratory of the St. Louis University before being released for sale.

Supplied in boxes of 6 ampoules of 1 c.c. (50 Doisy rat-units per c.c.)

FURTHER PARTICULARS OF THESE TWO PRODUCTS WILL BE SENT ON REQUEST.

Ankle and Foot Dressing

MODERN BANDAGING TECHNIQUE

In the case of any injury which involves muscles, joints, or ligaments, bandaging with Elastoplast affords, *par excellence*, the last word in effective treatment.

Elastoplast Elastic Plaster is not only the proved cure for Varicose Ulcer, but it is also ideal for all surgical and orthopaedic work.

Semiplast— a new idea in elastic plaster. Ideal for Varicose Veins and all support, as only the first turn of the plaster comes into contact with the skin.

Also **Elastoplast Wound Dressings** combining medicated gauze and lint pads with the elastic plaster base. They provide speedy and efficient dressings for cuts, wounds, incisions, boils, etc.

Elastoplast
Patent No. 253,527.

BRITISH MADE.

NEW WORK. *NOW READY.*

THE CAUSE OF CANCER

By **W. E. GYE**, M.D., and **W. J. PURDY**, M.B.,

Members of the Scientific Staff of the National Institute for Medical Research, London.

Since he published the results of his researches into the cause of Cancer six years ago, Dr. Gye, with the collaboration of Dr. Purdy, has repeated and amplified his experiments, and has made discoveries which, he holds, support his conviction that cancer is a parasitic disease, due to a filterable virus. These experiments are described in detail in the present work, with an abundance of elucidatory diagrams.

The Authors devote their first section to a lucid and trenchant discussion of the problem of malignancy. The last section consists of a general review of the whole question of cancer causation, ending with the conclusion that cancer is a cell reaction to a living intracellular virus, the reaction manifesting itself in cell growth and multiplication.

ANTI-TYPHOID-PARATYPHOID (T.A.B.) ORAL VACCINE

Administration of this protective vaccine by mouth is now an established alternative to the usual hypodermic method for immunisation against the enteric diseases, and has the advantage of avoiding all reaction.

This method is especially indicated where rapid immunisation is desired, as in the case of contacts; or when facilities for hypodermic injection are lacking.

Issued in packages containing three doses of killed emulsion, with three bile tablets for oral administration on three successive mornings. Full instructions accompany the package. Price 17/6 per set.

KEEP YOUR POWDER DRY

Manufacturers of Tooth Powders are accustomed to advance strong arguments for the use of dry powder as a cleanser of the mouth and teeth. It cannot be denied that a powder, if not too abrasive, forms an excellent polishing agent. And for this reason, a powder compounded of specially selected materials of exact quality and texture forms the polishing agent in Gibbs Dentifrice. It loses none of its efficiency by being combined with a saponaceous base. Indeed the saponaceous base of Gibbs Dentifrice tends to counteract any possible harshness, adds materially to the cleansing efficacy, and dispenses with one of the greatest disadvantages that a raw Powder exhibits; namely, wasteful messiness.

That is why Gibbs Dentifrice has won the wholehearted support of leading Medical authorities. By providing the public with a thoroughly safe and efficient dentifrice, and by giving it the widest publicity in the national press, Gibbs makes a valuable contribution to the cause of preventive dentistry. But in all Gibbs propaganda, the indispensability of the Doctor and Dentist is made perfectly clear. In fact, the most frequently recurring phrase in Gibbs Advertising is "Visit your Dentist twice a year, and use Gibbs Dentifrice twice a day.

GIBBS MOUTHWASH

A Peroxide Mouth Wash in Powder form. A new Preparation by Gibbs that has met with instant success.

Gibbs Mouth Wash produces Oxygen in the mouth, which has a wonderfully efficient cleansing and antiseptic effect; and definitely purifies the breath.

Although intended for twice daily household use, Gibbs Mouth Wash provides an excellent and safe mouth wash for use following extractions.

Gibbs Dentifrice

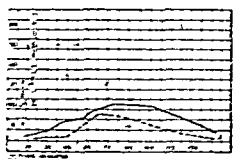
HORLICK'S MALTED MILK . . .



falls into the series of more digestible mixtures

Horlick's is a partially predigested milk food containing the mixed carbohydrates lactose, maltose and dextrin, and forming a light, flocculent curd on contact with the acid gastric juice. When breast milk fails, or when breast feeding is impossible, some modification of cow's milk is generally employed as the baby's food. But artificial feeding, to be successful, must be individual, and recent years have seen a marked increase in the number of artificial foods offered for the physician's choice. Where the digestive powers are below normal and impaired, and where, from any cause, a low fat diet is indicated, Horlick's is invaluable. Experience shows that there is no better choice than Horlick's Malted Milk for complementary and supplementary feeding, and for premature, delicate and under-nourished infants generally. Horlick's Malted Milk Co., Ltd., Slough, Bucks.

OVALTINE

WHEN SLEEP IS DIFFICULT

Judged by the numerous reports received from physicians and also from grateful patients, the use of "Ovaltine" for ensuring sound refreshing sleep deserves the widest recommendation.

It has been remarked that a more helpful prescription could not be wished for because:

1. Taken last thing at night before retiring it exercises a pronounced sedative effect and one that is natural in every sense.
2. It has a pleasantly soothing action on the stomach and nervous system, and does not cause the slightest digestive unrest, or occasion constipation.
3. It promotes a sufficiency of healthful sleep without resource to hypnotic drugs.

"Ovaltine" is a delicious concentrated extraction of malt, milk, and eggs, in the form of golden granules, which dissolve instantly in milk.

A liberal supply for clinical trial sent free on request.

Works: KING'S LANGLEY, HERTS

SHU.—The personification of sun, light, air, dryness, etc

". . . . the ideal antiseptic."

(Lancet, 1931, 1,323.)

There is a wealth of clinical evidence, accumulated over a period of years, in support of the view, now widely held, that Acriflavine is the ideal antiseptic for use in many conditions of common occurrence in general practice—for example, in gonorrhoea, impetigo, psoriasis vulgaris, meningococcal septicaemia, typhoid fever and in undulant fever.

A brochure containing excerpts from the medical press indicating a variety of conditions in which Acriflavine 'B.D.'—the original British Acriflavine—can be employed with advantage, will be sent post free to any physician on application.

FEEDING IN CACHECTIC DISEASES

Owing to its chemical combination of casein and sodium glycerophosphates Sanatogen is of the utmost value in cachectic diseases. Sanatogen introduces casein into the organism, in a form in which it can be assimilated even by patients with greatly decreased powers of absorption. At the same time the glycerophosphates regenerate and strengthen the whole system.

IN TUBERCULOSIS:

Sanatogen increases the weight, has a strengthening influence on the nerves, enriches the blood and overcomes the "run-down" feeling of the patients ["British Journal of Tuberculosis."]

IN SYPHILITIC CACHEXIA:

Sanatogen overcomes the nerve-weakening influence of the specific treatment [Col. Lambkin in "The Lancet," Vol. CLXXI, No. 4340.]

Nutritional anaemia in infancy

IT has recently been shown that breast milk does not contain an adequate amount of iron and that from the early days of infancy it is necessary to supply iron to the organism, if healthy development of the child is to be attained.

The organic iron in Virol from Glycerine Extract of Red Bone Marrow and from yolk of eggs is absorbed with ease.

The vitamin-containing Fats are very finely emulsified; they are therefore, easily digested by the most sensitive alimentary tract at all ages, including earliest infancy.

All experience goes to show that Virol is a food of marked value in a great variety of conditions in which adequate nutrition by ordinary means is not easy to secure.

"EULAXASE"

For the

Rational Treatment of Constipation

"Eulaxase" is a new preparation, in tablet form, for the treatment of constipation. The tablets contain biliary and intestinal secretions, with agar-agar and lactic ferment (bacillus acidophilus), enclosed in a special coating of activated charcoal. The essential advantage of "Eulaxase" is that it provides a special substitute for each of the chief factors that are deficient in intestinal stasis. In other words, it forms a natural, complete, and efficient means of treatment for constipation.

In bottles of 60 tablets for prescribing, and 600 tablets for dispensing.

Descriptive leaflet will be sent on application.

British Buying Begins at Home

From all quarters there is an appeal to the public to assist the country in the present emergency by demanding the products of British labour, so that we do not import one shilling's worth of goods more than is necessary.

NATIONAL MARK MALT EXTRACT WITH COD-LIVER OIL is manufactured from the finest home-grown barley and pure cod-liver oil on premises subject to Government inspection.

It is guaranteed to be of a uniformly high standard of quality and of standardised content in its principal constituents. It must contain not less than 5% soluble protein, be of at least 1·4 specific gravity, thereby ensuring a high proportion of carbohydrates, include 15% cod-liver oil and have as a minimum 25 Lintner diastatic activity, thus conserving the valuable accessory food factors.

It is certain to give satisfaction and to offer the best value for money.

National Mark Malt Extract is markedly superior to cheaper imported brands of malt extract with varying constituents which make accurate prescription impossible.

National Mark commodities are nationally advertised and widely recognised as home produce of dependable quality.

A natural

COD LIVER OIL CONCENTRATE

containing both vitamins

A *and* D

in a pleasant tablet form

The Vitamins A and D in their intimate natural association are the essential and vital principles of Pure Cod Liver Oil. The fats in the oil are of relatively small importance and are, in fact, disadvantageous in the numerous cases of fat intolerance.

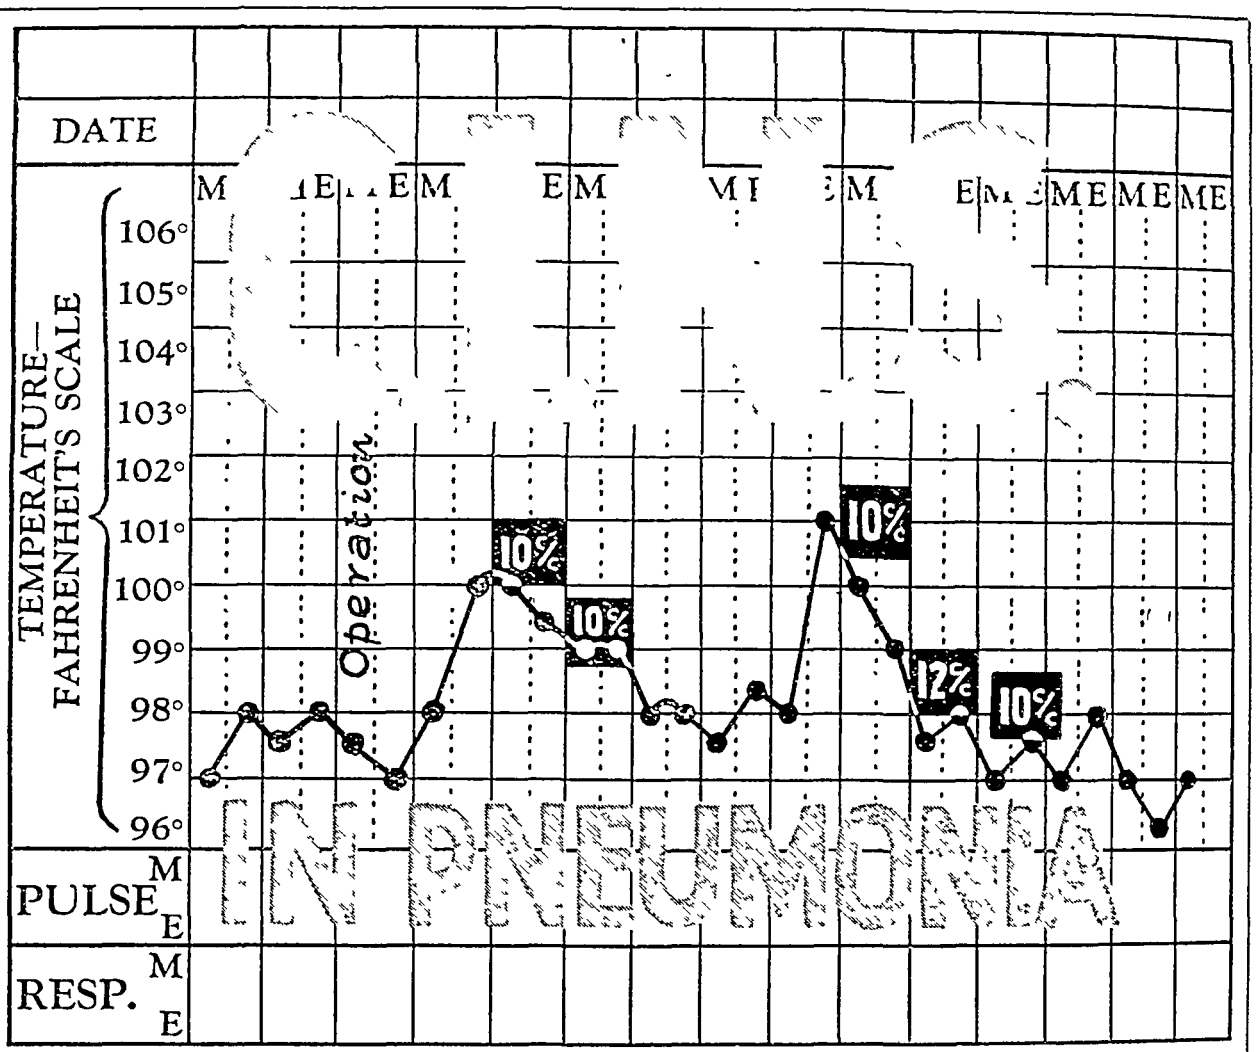
White's Cod Liver Oil Concentrate represents 100% of therapeutic efficiency. Each tablet contains not less than 500 vitamin A units when essayed for xerophthalmia and 200 vitamin D units when essayed for rickets by the McCollum Line Test; equal to a teaspoonful of a high-grade Cod Liver Oil.

White's Cod Liver Oil Concentrate is a *natural and not a synthetic product*—a matter of the greatest therapeutical and clinical importance. The potency and stability of each tablet is guaranteed. Its small bulk (only 1% of the oil), great palatability and very ready digestibility are appreciated by patients of all ages.

Indications—Tuberculosis. Rickets. Anæmia. Malnutrition. Infantile Weakness. Deficiency Diseases. Nervous Diseases. Wasting Diseases. Respiratory Diseases. Adult Weakness.

And, wherever COD-LIVER OIL is indicated.

Unlike emulsions, these tablets contain no gum or objectionable flavouring matter, and they cause no nausea or irritability. White's Concentrate of Cod-Liver Oil Tablets are extremely palatable, and being of small size, they are very easily administered, for instance, one tablet is fully equal to the B.P. dose of Cod-Liver Oil for a child.



Every physician interested in Cod-Liver Oil Medication is invited to send for a full Clinical Sample free of charge.

LIVER THERAPY PER OS

HEPATEX is the most efficacious Liver Extract for administration per os. It contains the principle active in pernicious anaemia and in addition the full Vitamin B complex. Hepatex is a proved remedy not only for pernicious anaemia, but is also of considerable value in other anaemic conditions. It is so concentrated that one fluid drachm is equivalent to two ounces of fresh liver.

Issued in 4-oz. bottles.

HEPATEX WITH IRON has been introduced for the treatment of those cases of severe secondary anaemia where a combination of liver and iron is indicated. The special form of iron used is greatly superior to standard iron preparations as regards assimilation and absence of gastro-intestinal disturbances. A dosage of one or two fluid drachms a day gives a most satisfactory response.

Issued in 2-oz. bottles.

LIVER THERAPY BY INJECTION

HEPATEX P.A.F. has been introduced by us for the injection treatment of those cases of pernicious anaemia where speed of action is essential. It is presented as a highly concentrated, non-toxic solution, which on injection produces an immediate reticulocyte response. Cases of pernicious anaemia with red cell counts as low as 600,000 have responded satisfactorily, and the need for blood transfusion is entirely obviated. It is also useful where liver administered orally is not tolerated. The dose varies from 5 c.c. intravenously per day to 5 c.c. intramuscularly per week, according to the clinical condition.

Issued in 5 c.c. ampoules.

Further particulars will be sent to Physicians on application to

Petroleum

in the treatment of

Intestinal Disorders

Purified Petroleum in one form or another is becoming more and more widely employed in the treatment of intestinal disorders associated with toxæmia To obtain the best results, the petroleum should be not only non-irritating and free from all impurities, but it should preferably be in the form of an emulsion. In this form, the minutely divided petroleum globules mingle freely with the intestinal contents, and are more widely and evenly distributed throughout the entire intestinal tract. Maximum lubrication is thus assured and the characteristic action of the oil obtained with greater uniformity.

Angier's Emulsion is made with a specially purified petroleum of just the right degree of viscosity. It is a perfect Emulsion of cream-like appearance and consistency, and mixes instantly with water and other liquids. Pleasant to the palate and remarkably well borne by sensitive stomachs, it can be administered either undiluted or in any suitable vehicle. It has been found that patients who cannot tolerate clear petroleum are able to take Angier's Emulsion without the slightest difficulty, and continue indefinitely without ever developing an antipathy to it. Angier's Emulsion will also be found most useful as a vehicle for the administration of intestinal antiseptics or astringents, for which purpose it is eminently suitable.

"After long experience of many forms of paraffin and petroleum, both in the character of emulsions and otherwise, I have found none so satisfactory to the patient as Angier's Petroleum Emulsion."

—M.D., D.Sc., M.A.

CHURCH AT BRADFORD-ON-AVON BUILT BY EALDHELM OR ALDHELM, A PIONEER OF LATIN LEARNING IN THIS COUNTRY.—Aldhelm, first great scholar of Anglo-Saxon England, was a pupil of Hadrian, at Canterbury, and later of Maidulf, a famous Irish scholar settled among the West Saxons at Malmesbury. He studied Roman law, astronomy, astrology, the art of reckoning, questions connected with the calendar, and even Greek and Hebrew. Bede writes that he was "of marvellous learning, both in liberal and ecclesiastical studies." He wrote poetry in Anglo-Saxon and set his verses to music. Further, he did much to promote an intellectual Golden Age in England. Aldhelm not only taught but founded monasteries where scholars inspired students to learn without leaving their own shores. Among the many churches which were built by Aldhelm, or inspired by him, is the fine and still existing monument of Saxon architecture here reproduced. So large became the Wessex diocese that it had to be divided, Aldhelm becoming the first Bishop of Sherborne.

A New Departure in Cigarette Manufacture

du Maurier

VIRGINIA

with the exclusive filter-tip

The Ministry of Health (Memorandum to Local Authorities, 8th Series). "No evidence has been adduced to support the contention that the mere inhalation and exhalation of tobacco smoke is of importance, although two possible causes of 'irritation' are *heat* and the *products of combustion.*"

The Claims of the Manufacturer

I. The filter-tip is selective in its action and while permitting the full passage of all the desirable constituents, shows a high capacity for retaining both the pyridine bases and non-volatile bodies, which undoubtedly form the principal source of throat irritation.

II. Unfiltered smoke is as dangerous as unfiltered water and as irritating as dust-laden air. The filter-tip effectively purifies tobacco smoke from harmful irritant and acrid substances which are inevitably formed when tobacco leaf, even of the finest quality, is burned.

III. By the introduction of the filter-tip the palate loses nothing, but the voice and throat gain immeasurably as the irritants are held in check without impairing the flavour or delicate character of the smoke. This is the central advantage to be gained from the filter-tip

IV. Cigarettes containing this filter-tip will be welcomed both by the medical profession and the public as a valuable means of preventing "smoker's cough" and other adverse effects on the pharynx, larynx or general health, traceable either directly or indirectly to the irritants and acrids in tobacco smoke.

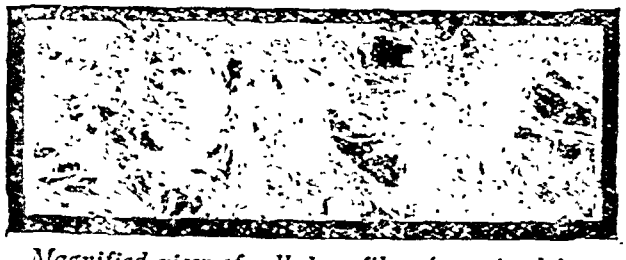
V. They constitute the only safe form of smoking for those predisposed to, or suffering from, pharyngitis, laryngitis, or any form of bronchial or respiratory affection. They are invaluable in cases of gastric trouble due to tobacco tar.

A Selection from many Authoritative Endorsements

The aim of *this ingenious filter* is to trap the irritating pyridine derivatives and other non-volatile bodies, while permitting free passage of the agreeable volatile constituents of tobacco smoke.

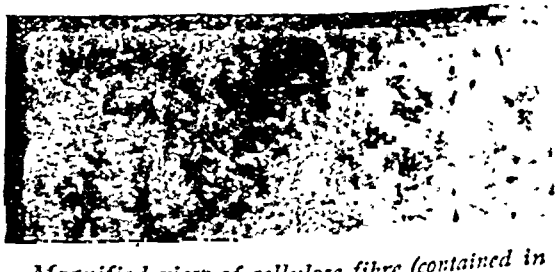
The British Medical Journal, April 18th, 1931. p. 692.

A filter-tip must not only be efficient as a filter to irritating and noxious products, but must not affect the flavour . . . pyridine, the most offensive constituent of tobacco smoke, and other non-volatile irritant substances are retained by the ingenious filter-tip which is used in du Maurier cigarettes. From a personal trial we can testify to the *pleasant flavour and aroma* and to the *distinct lack of irritation* experienced in smoking these cigarettes.



The Practitioner, May, 1931. p. 584.

We have tested these cigarettes and find them to be *cooler* and *less irritating* to the mucous membrane than ordinary cigarettes of good quality without the filter-tip.



The filter-tip . . . retains bodies which are generally held to be the principal cause of throat irritation. Additional advantages of the filter-tip comprise *protection of the lips, teeth and fingers from unsightly stain,* and prevention of fragments of tobacco from getting into the mouth.

The du Maurier cigarettes may be regarded in every way as satisfactory, and they constitute a distinct and hygienic advance in the marketing of cigarettes.

The Lancet, January 24th, 1931. p. 194.

Magnified view of cellulose fibre (contained in the filter-tip). BEFORE SMOKING.

Magnified view of cellulose fibre (contained in the filter-tip). AFTER SMOKING.

'du Maurier' Virginia Cigarettes at 20 for 1/-, 50 for 2/6. Obtainable from your own Tobacconist or from Peter Jackson, 217, Piccadilly, London, W.1.

Observations on TRIGEMINAL NEURALGIA*

BY

GEOFFREY JEFFERSON, M.S.(Lond.), F.R.C.S.

HONORARY NEUROLOGICAL SURGEON, MANCHESTER ROYAL INFIRMARY; HONORARY SURGEON, SALFORD ROYAL HOSPITAL.

In introducing the subject of paroxysmal trigeminal neuralgia I shall omit any references to the nature of a disease the causes of which are as unknown to us as they were to Tudor physicians. But it will be necessary at the outset to make some allusion to the character of the paroxysms, because adequate treatment depends on the selection of the right cases. Not uncommonly patients are referred as "neuralgias" who undoubtedly have pain in the face and head, yet who are not true sufferers from the paroxysmal disorder, and these may be made much worse by procedures very right and proper for the orthodox case. As to these procedures, the present occasion is important because the time has arrived for a reassessment of values in the methods of treating this condition. The claims of alcohol injections have been most ably and convincingly pleaded in this country in particular; but sufficient evidence is now available to show that operation is in general superior to injection, and should therefore be more widely employed. Alcohol has its place in the treatment of neuralgia, but it must be removed from the dominance which it has held. I shall elaborate the logic of these statements later in this discussion.

CHARACTER OF PAROXYSMAL TRIGEMINAL NEURALGIAS

Although the character of the attacks of pain in true paroxysmal neuralgia is familiar enough, yet an outline of the chief features will not come amiss, for in its severe forms it is not a common occurrence, being slightly rarer in my experience than intracranial tumours. If reflex neuralgias from various local causes were added, they would no doubt more than adjust the numerical balance. Clearly, comparative experience must vary, but I believe that I am correct in the main on this point.

Sex.—The predominance of neuralgia in females has long been recognized, but since we do not know the cause of the disease no important conclusion may be drawn, nor is the sexual disparity sufficiently marked to lead in itself to any special deduction.

Unilaterality.—The pain is always confined to one side, and generally to one division at the commencement, either the second or third. Sometimes the pain affects two divisions very early, but, as a rule, it remains limited at the beginning and only spreads after months, or often years, have elapsed. The pain keeps within the confines of the trigeminal field, and spread outside it into the neck or shoulder will make us suspect some other cause, though overflow is sometimes genuine. In some cases it may reappear on the opposite side, limited to a single division, generally the second. As the pain may appear on the opposite side long after it has been successfully treated on the primary side, the sparing of the motor division is a wise precaution at operation. Fortunately, this step in no way increases the likelihood of recurrence, nor is the resultant anaesthesia any the less.

Nature of the Paroxysm.—The pain is always of brief duration, and when the storm has passed the patient is generally comfortable, though sometimes a tingling or stinging sensation endures. But whether this slight middle pain is present or not, the patient lives in dread of a return of the torment, and even after successful treatment this apprehension of the future persists for a long time. The pain is brought on by a touch, by a breath of wind, by a movement, so that smiling, talking, and eating become a penance. A facial pseudo-palsy develops in some patients; the face becomes almost Parkinsonian in its mask-like appearance, actually a purely voluntary defensive inhibition. The patient sometimes swathes herself in wrappings and brings with her someone to talk for her, a "talker," in the same way that a disabled batsman at cricket may be allowed a "runner." The descriptions of the nature of the pains vary somewhat, but it is clear that neuralgic pains are sharp, and lancinating, like long needle thrusts or stabs. It is probable that the differences in neuralgic pains are differences of description rather than real disparities in essence, and vary with the patient's powers of expression. This point is important, and may be useful in diagnosis, for if we can standardize, as it were, neuralgic pains, we can more easily differentiate between true "neuralgias" and those who suffer from pains in the face of another kind. Certain it is that the pain is essentially different from the more common burning, throbbing, duller, and continous pain of an inflammatory lesion, and when a person who is thought to have neuralgia uses such terms as the last to describe the pain, we shall rightly suspect that we are faced with something other than true trigeminal neuralgia—very possibly a closed infected antrum with secondary neuralgia. In much the same way that the pain is differently described by different persons, so the expedients to which they resort to mitigate, or to prevent, the attacks vary with individual ingenuity and resources.

Facial Spasms.—The term "tic douloureux" is not a good generic title, as in many patients facial spasm is not an important feature. Often during severe attacks the pain causes irregular contractions of the facial musculature, but they are seldom of a severely spastic or clonic nature. Painful cramp-like facial spasms may occur in cases which are not essentially due to trigeminal neuralgia, spasms which are not stopped until the seventh nerve is blocked. These cases are very rare, but must be distinguished as a separate entity. In trigeminal neuralgia the pain comes first and facial movements are secondary, followed as the pain passes off by lachrymation, salivation, and flushing of the capillaries of the face (a sympathetic phase).

Remissions and Intermissions.—As already mentioned, the painful spasms are in general of brief duration; hence the pain commonly disappears altogether for long periods. In fact, remissions of symptoms are as characteristic of major neuralgia as they are of duodenal ulcer. This is a fundamental characteristic. The pains may disappear for weeks, months, or even years; and here we have the explanation of the fact that so many patients are able to give such long histories of their malady. Generally this is well recognized by the patient, who admits that were it not for the free periods he would have gone out of his mind or sought death. At the same time the knowledge that after a few weeks or months of agony the pain will probably go, and the hope that it will not return, encourage the victim to struggle on with inadequate medicinal protection against his sufferings. With this must be coupled the undeniable fact that doctors themselves too often hesitate to advise radical surgical treatment. I shall refer to this point again later.

The remissions from pain are most irregular, and although in some patients there is a seasonal incidence in spring and autumn, this is by no means general. Cold in my own series has been more beneficial than heat, and there is little hope that a stay in a warm or sheltered watering-place will give the relief so eagerly sought, and sometimes found in other chronic diseases.

* Read in opening a discussion in the Section of Surgery at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

Sites of Election.—The pain of trigeminal neuralgia is generally strictly anatomical in its distribution. In my cases it has commenced rather more often in the second division. Probably the second and third divisions are affected more or less equally, but the slightly greater incidence in the second division in my own series is worth noting, because it used to be taught that neuralgia began in the third division and spread upwards to the second. This is certainly not the rule.

First Division.—A point on which there can be no dispute, however, is that the first division is rarely affected first (2 per cent. of my series). Many patients with severe neuralgia complain of pain passing up through the eye to the forehead from the second division, but this is a pure overflow and stops when the pain in the lower part of the face is put to an end. Further, pain high in the temple may originate in the auriculo-temporal branch of the third division and from the zygomatico-temporal branch of the second, and may be described by our patients, who are not anatomists, as "pain in the forehead."

The freedom of the ophthalmic division from primary neuralgia is of immense importance when we come to treatment, for it is evident that we can, if we choose, omit this part of its predestined deep fibres from destruction without fear of subsequent pain in this area. The recognition that this branch can be spared has profoundly modified the surgical treatment of neuralgia.

Second Division.—The pain is generally in the soft parts of the face, and especially in the upper lip and beside the nose. It may also affect the gum about the canine fossa, but does not often spread to the palate. Second division neuralgia tends, therefore, to be seated in the soft parts, and is, if one may call it so, an anterior pain. It may, of course, extend into the full distribution of the second division, including the posterior palatine nerves, the upper gum, the temple, as already mentioned, the side of the nose and the eye, and overflow beyond these confines on the same side but not to the other. On the whole, however, the presence of pain in the upper lip and the fear of the lip and cheek being touched are the striking features of neuralgia in this division.

Third Division.—The pain in neuralgias of this division is chiefly in the bone and gum, going back to the tragus but not so often into the lip or tongue. Indeed, the freedom from severe pain in the tongue is notable; even in well-established cases it may dart there only occasionally. Third division pain is therefore more often a deep-seated pain and is not so tiresome in the lip as with the second division, though the pain is in itself no less severe.

"Atypical Neuralgias."—In very marked contradistinction to the above is a most difficult group, which is at present classified under the non-committal title of "atypical neuralgias." The outstanding feature of these cases is the non-paroxysmal nature of the pain, which is continuous night and day, often for years. It is described as a burning and often as of a pulling kind, and is generally felt all over the trigeminal field and often beyond it from the start. The pain is equally described as unbearable, but it never remits and it never causes those sudden eloquent silences, those postures and anguished expressions which are diagnostic of true neuralgia. In fact, when the patient, in the course of describing the pain which has been so continuously present, is interrupted and asked whether the pain is there now, the invariable answer is, "Yes, of course, it never ceases," although his demeanour has given the clinician no special inkling that he was indeed in pain at the time. This is quite [illegible]. The patients are generally younger than the [illegible]," often in the twenties or thirties, an age at which paroxysmal neuralgia is rare, though [illegible] unknown. Further, the pain is often centred about the eye and affects the forehead and scalp more than the rest of the face, radiating to the neck, shoulder, and arm. Both sides are commonly affected, though one may be much less troublesome than the other. It is important that we should differentiate this type because surgical treatment is entirely useless, and *indeed should be* avoided, as it commonly makes the condition worse since all treatment for pain is essentially destructive. Such steps give the patient a positive lesion with which to tempt some other surgeon to extend the damaged area in the hope of cure—a praiseworthy but vain aspiration. (See excellent reviews of this subject by Glaser and by Stewart and Lambert on spheno-palatine neuralgia.)

Glosso-pharyngeal Neuralgia.—This is a rare disease but one which is easily confounded with trigeminal neuralgia. There has been only one case in my series, and this will be separately reported. The pain is equally spasmodic, but is generally localized to the depths of the ear and to the fauces or to one or the other, an elective tendency; it does not spread to the face. If such a distribution is localized to the ear, it may delude the surgeon into thinking that it is a curiously local example of third division neuralgia, seated in those twigs which supply the tragus, auditory meatus, and tympanum. The pain is more localized and more deeply seated than in trigeminal neuralgia, and is brought on not by chewing and moving the jaws but by swallowing. The treatment is of course resection of the glosso-pharyngeal nerve.

Post-herpetic Neuralgia.—Brief mention must be made of post-herpetic neuralgia. It is well known that herpes is a distressingly painful affection, but in the young or moderately young it passes off without any legacies but scars. In the aged it is almost always followed by pain of the most insistent and wearying nature. This pain, like that of the atypical neuralgias of younger persons, is continuous and unremittent, and it is my experience, and the experience, I think, of all of us, that long-standing continuous pain is intractable to surgery unless it is secondary to chronic malignant disease. Occasionally post-herpetic neuralgia is spasmodic, and in such cases there is more hope of surgical cure.

Tumours and Gummata of the Gasserian Ganglion.—Lastly we have those cases in which pain in the trigeminal field is caused by tumours or focal lepto-meningitides affecting the root of the nerve in the posterior fossa, by tumours or aneurysms involving the ganglion in the middle fossa, or by nasopharyngeal or other growths infiltrating the issuing divisions. The differentiation of neuralgias due to these conditions is a fascinating subject, but it has no place in the present discussion. Fortunately we have a touchstone by which these causes can generally be eliminated immediately, namely, anaesthesia or analgesia of the affected area. In true paroxysmal neuralgia there is never any alteration in the sensory perception of the skin, unless it be a certain hypersensitiveness. This is a fundamental point in diagnosis. If cutaneous anaesthesia is found [illegible] (anaesthesia dolorosa), then we know at once that the case is one in which there is some definite lesion of the trigeminal or its branches, and a full study must be made to discover the cause. I am aware that [illegible] acoustic neuromata have been discovered [illegible] the course of an attack through the posterior [illegible] sensory root of a patient thought to be the subject of plain neuralgia. But such isolated experiences [illegible] my opinion imply, as some would have [illegible] this is a sufficient reason for the routine [illegible] approach. The fact is that neuralgia [illegible]

leading symptom in lateral recess tumours. Severe neuralgic pain sometimes occurs in malignant disease of the mouth, and no little success may be obtained by a well-planned nerve section, which gives astonishing relief. Mention must be made of trigeminal neuralgia, often with a large overflow, occurring in disseminated sclerosis. These cases can be helped by surgery. The causal lesion seems to be a patch of sclerosis in the pons in the area of entry of the sensory root (Parker).

Differential Diagnosis of Paroxysmal Neuralgia

The foregoing account should make clear enough the characteristics of major or paroxysmal neuralgia, and also those states most likely to incite it as an auxiliary phenomenon. To recapitulate: the patient is usually female, the pain is limited to one or two divisions save in the worst cases, the attacks are of brief duration, and between the pains the patient is moderately comfortable though apprehensive. There is a strong tendency towards remissions in which the pain is negligible or entirely absent for weeks or months. There is no alteration in the sensibility of the skin, certainly no diminution. The pain of secondary neuralgia is very similar, and when due to dental causes it is easily remedied. Antral infection, however, is more insidious. It might be assumed that if pain corresponding to the paroxysmal type has been present for a long period, possibly for two or three years, and there is no history obtainable of disease in the nose or of purulent discharge, paranasal infection cannot be present. This would be an unsafe conclusion, for I have known of such cases, and I firmly believe that *x*-ray studies of the sinuses should be made as a routine if error and disappointments are to be avoided. Generally these infected patients admit having had occasional swelling of the face or, what is more important, of the lids, an oedema lasting for a day or two. Flushing and a sensation of subjective feeling of swelling occurs in some paroxysmal cases due to disturbance of sympathetic control during the attack. This is of short duration and may usually be distinguished from a real oedema.

Treatment

It is just forty years since Horsley published a paper entitled "Remarks on the various surgical procedures devised for the relief or cure of trigeminal neuralgia." All the operations there reported, thirty-one on nineteen patients, were peripheral save one—a "section of the fifth nerve from the bulb" by a transtentorial approach ending fatally. The years that have passed have seen many further stages in the struggle between the surgeon and a nerve which shows the most astonishing and obstinate powers of regeneration, powers which would delight us if they were reproduced by, say, the median or ulnar at the wrist. The story of the surgery of neuralgia is one of a slowly advancing attack from the periphery inwards to the ganglion and finally to the sensory root. The names of many famous men are associated with this movement, especially Rose, Horsley, Krause, and in particular Jonathan Hutchinson junior.

Operations on Gasserian Ganglion

Hutchinson perfected the removal of the lower two-thirds of the ganglion with the preservation of the ophthalmic division and that portion of the ganglion which is proper to it. This he did for three reasons: first, because primary neuralgia is rare in the first division and when present is generally an overflow, so that the division may usually be left intact; secondly, in order to preserve sensation in the eye and to prevent the neuro-paralytic keratitis which is so apt to follow complete denervation of the cornea; and thirdly, because by leaving it he avoided the chief danger of the operation at that date, injury to the cavernous sinus. Hutchinson brought this operation to a high pitch of efficiency, for in 1919 he reported 70 partial excisions of the Gasserian ganglion with 3 deaths (4 per cent. mortality) and refers to Horsley's (1908) 120 cases with 6 deaths (5 per cent.). Horsley's final figures were never, I think, published. These English figures compared extraordinarily favourably with those from foreign clinics, and were unquestionably far better than those of surgeons with less experience in British and other centres.

The Gasserian ganglion in its upper and anterior part lies in the wall of the cavernous sinus, the ophthalmic division penetrating it. The whole ganglion cannot be removed without injuring the sinus, and misguided attempts to do so were responsible for the heavy operative mortality that years later still hangs like a cloud over the subject. Hutchinson's operation was well conceived in that he removed only such part of the ganglion as could be extirpated without opening the cavernous sinus, though even so, a small opening is almost inevitable when the cut second division is stripped back. None the less the Hutchinson operation has been abandoned in favour of another of which he was himself, curiously enough, extremely sceptical. I refer of course to section of the sensory root by the temporal extradural route, the advantage of which is that the cavernous sinus is not a hazard at all, for the operation has nothing to do with it.

Methods of Division of Sensory Root

This operation, generally credited to Spiller, has been perfected by his surgical colleague Frazier, who has recently recorded 511 cases, with 1 death in the last 269 cases (0.37 per cent.). Prior to this, Cushing in 1920 had reported 332 Gasserian operations with 2 deaths (0.6 per cent.), most being root sections, others partial gasserectomies. Similar figures have been recorded by Adson. Cushing's statistics certainly provided a tremendous stimulus, for ten years ago his low mortality rate in such a large number of cases seemed well-nigh incredible.

Three innovations have contributed to the improvement in operative results: the sitting posture in the dental chair, the use of illuminated retractors, and, lastly, the employment of suction as a means of keeping the field clear.

I have personally performed the operation on eighty-five occasions with two deaths, one from an unknown cause early in the series in an exceedingly bad subject, the other a death from pulmonary embolism on the ninth day in a patient making the usual smooth post-operative recovery. This mortality is higher than I would wish, but it is only common sense to admit that occasional fatalities must occur when we are dealing with persons of the age and debility of some "neuralgias." Neither of my deaths came from technical error, and indeed it is my purpose in this address to show that the factors which can bring about morbidity and fatality are so few that such deaths as occur may be attributed more to bad luck than to the inherent hazards of the operation. I have carried out fractional root sections five times under local anaesthesia (which has its special points), helped out by a little inhalation anaesthetic when the root was being worked upon. And I have twice cut the sensory root on the second side, preserving the motor root, after the ganglion on the other side had been destroyed by alcohol by the Härtel method. The precise mortality in decimal points of zero is not of great importance: what is important is

that it is clear that with good surgery and good fortune only one patient in a very large number is going to die after the operation. Yet it would seem that practitioners the world over still think of Gasserian operations as having the same mortality as in the immediate post-Listerian period, or so one would judge from their attitude towards it. It is a fact, of course, that the operation of section of the sensory root is a very difficult operation to learn and is at times an exceedingly difficult operation to perform, though at other times it may be simple.

It is clear from the low mortality of this operation in large series of cases that there must be something essentially benign, some factor of risk must be lacking, as compared with even the partial Hutchinsonian resections. This logical assumption is correct and it lies in the avoidance of any likelihood of damage to the cavernous sinus. It is true that the sinus and even the carotid artery may be damaged in this operation with fatal results, but only when the surgeon has gone astray, and these structures are not normal risks when the operation is well performed. The sensory root can be picked up at the posterior end of the cavum meckelii and the actual section carried through without the least loss of blood. It is imperative that the field should be entirely dry before the final exposure of the root in its cerebro-spinal fluid sac, and it is in effecting this that the surgeon may have to use all the skill at his command, not because of bleeding from the cavernous sinus but of bleeding from veins in the dura. Some individuals have none of any note, others may be well endowed.

Advantages of Fractional Division

Total division of the sensory root, however, is open to the dangers that come from an insensitive cornea and is in this respect inferior to the Hutchinsonian operation, though superior to it in point of mortality. Realizing this, Frazier has applied the Hutchinsonian principle to the root section, preserving those fibres in the root which supply the eye, and Adson has added a further refinement in the preservation of the motor root. This operation, which is now the accepted standard operation among neurological surgeons and the one which I perform, is referred to as "fractional division of the sensory root." It is fortunate, indeed, that the arrangement of fibres in the root of the trigeminal nerve allows, as Frazier has shown, of such manoeuvres being carried through with success. There is no doubt a slight interchange and a little interweaving of fibres, more in some individuals than in others, but in the main the fibres preserve a predestined course in the root, those to the ophthalmic division lying innermost and above, those to the third division lying below and outside, those to the second occupying an intermediate position. The parallel arrangement of the fibres is well shown in Fig. 1. The motor root lies behind the sensory, crossing from above downwards, and is free from the sensory fibres in that part of the root exposed at operation. The safest way of preserving it is, in my experience, to cut through the root from without inwards with long fine Stille scissors, until a hole is made through which the motor root, running in a slightly different direction, is clearly seen. In cases in which alcohol injections have been made into the ganglion beforehand, a satisfactory fractional section is much more difficult to carry out, for there are many more adhesions, the fibres do not separate readily one from another as they ordinarily will, and the motor root is commonly matted to the sensory part. These are serious obstacles to clean operating, and it is desirable that we should attempt to standardize our treatment of neuralgic patients and avoid making ganglionic injections in patients who are suitable subjects for fractional section.

Results of Fractional Division

Personally I make a practice of dividing the lower [illegible] outer two-thirds (lower and outer because the root [illegible] obliquely with its flat upper surface looking upwards [illegible] outwards). The resulting anaesthesia affects the [illegible] two-thirds of the face and half the cornea. In many [illegible]

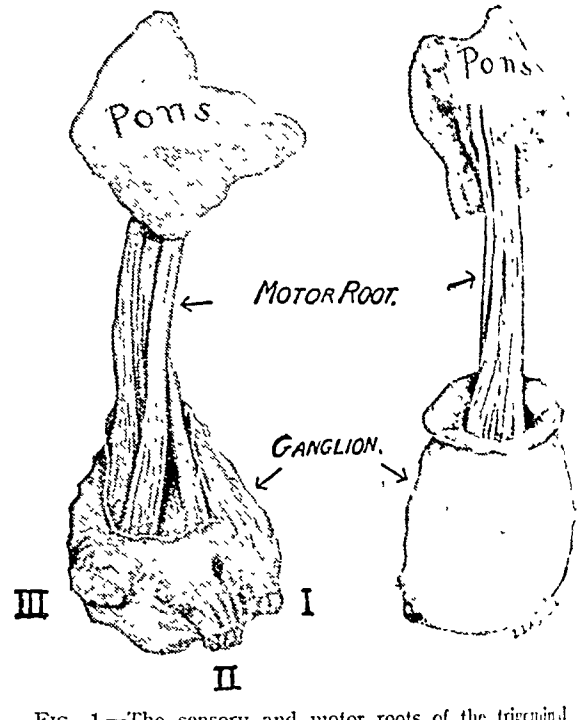


FIG. 1.—The sensory and motor roots of the trigeminal nerve, from below (left) and above (right). Note the parallel fibres in the sensory root.

the line of anaesthesia runs strictly through the pupil the lower half of the cornea being insensitive, the upper normal. Figure 2, which is the work of an entirely independent observer on cases operated upon by me, shows the average result. The retained sensation in the cornea has been sufficient to prevent the neuro-paralytic keratitis of which Paton made so masterly a review. From the recurrence in a series of cases of this picture of partial ocular anaesthesia it becomes abundantly manifest that we have in this operation a method of attack on trigeminal neuralgia which seems to meet all our needs. In two or three cases I have ventured with success to cut the middle

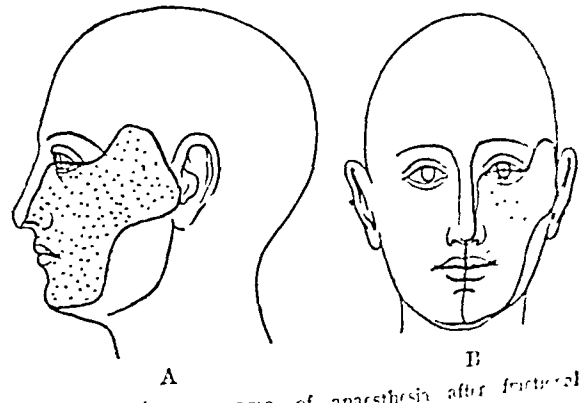

FIG. 2.—Average area of anaesthesia after fractional section of the sensory root. (F. N. Mu[illegible])

portion of the sensory root alone (see Fig. 3) in [illegible] whose chief pain was referred to the second divi[illegible] anaesthesia following partial divisions is never dense, b[illegible] the operation none the less stops the neuralgic pains. T[illegible] partial preservation of sensation is a great boon to t[illegible] patient. We have an anomalous situation in the pre[illegible] ence of sensation after fractional root division, for

anaesthesia is incomplete after an alcohol injection, the pain is almost certain to return (though there are cases in which it does not), on the other hand, if the face is not entirely numb in the painful area after root section it does not seem to matter No doubt the explanation is to be sought in the site of the interruption of conduction in the two operations It must be conceded that on occasions the motor root cannot be isolated with certainty, but its conservation should be aimed at Marshall's studies on my cases show that there is no lessening in the anaesthesia when it has been spared.

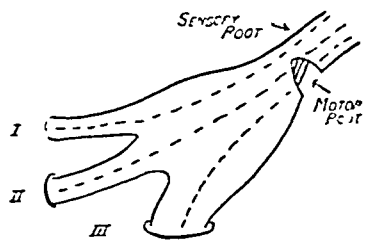

FIG 3—Diagrammatic schema of fractional root section with preservation of motor root Ophthalmic fibres preserved

It has been claimed by those who urge the division of the root in the posterior fossa by a cerebellar approach that fractional section stops the pain without producing a totally anaesthetic face This same result, in my experience, follows fractional section in the middle fossa, and is not a specific result of the immediately pre pontine section It is, indeed, a well recognized result of root section and partial nerve section elsewhere that analgesia is produced over a wider area than tactile anaesthesia

Alcohol Injections

In view of the mortality following Gasserian operations in the remote past it is not a matter for wonder that attempts were made to find some less lethal method of treatment Peripheral alcohol injections have proved their usefulness and in the hands of some, notably of Harris in this country, they have proved of great service I believe that it is wise to advise a patient to have at least one peripheral injection before proceeding to operation, especially in the less severe case clearly limited to one division The advantage is that he has a foretaste of the numbness (and that curious and frequently accompanying feeling of swelling) which will be permanent after the root section an anaesthesia which must always come as some thing of a surprise Pre operative advice, though useful, can never adequately describe the actual feeling However if a fractional root division is to be performed preliminary injections are not so necessary, as some sensation is retained As to injections into the ganglion itself, whether by Harris's lateral method of infiltration or by the anterior direct placement of alcohol into the ganglion and root as devised by Härtel, and developed by my colleagues Rayner and Morris in this country, I believe that this method should be restricted to those who are judged to be physically incapable by reason of their age or of coexisting disease to undergo operation I have arbitrarily fixed 70 years as a limit, but I have no doubt that even some older persons could be shepherded through a root section if it were necessary In younger persons and especially those in the forties and fifties, and those whom we term a "good" sixty or more, I have no hesitation whatever in saying that fractional root section is infinitely the better course The matter is capable, I believe of precise and logical statement If operation had nothing better to offer than a complete and dense anaesthesia of the face with the risks consequent on total interruption of the ophthalmic fibres, there would be nothing to choose between such an operation and alcohol injection —indeed, the balance would be in favour of the latter except after its repeated failure But fractional root section offers something which alcoholic destruction of the ganglion cannot give—namely, preservation at will of such fibres as we wish to keep This being the case there seems to me to be little room for argument as to which is the method of choice, though the exigencies of circumstances may at times induce us to use a method which is both theoretically and practically inferior Alcohol injections are in any case more uncertain than operation The not infrequent result of injections is that we achieve rather less than we hoped for, while at times, using a precisely similar technique, we obtain more, unfortunately, than we bargained for We must not forget that trigeminal neuralgia is a really serious affection, and we do not make it less serious by using a method which is to the casual eye a simple and innocuous one, and yet may require much repetition and bring about an occasional catastrophe But in the aged and the infirm we must continue to use this somewhat uncontrollable method

CHRONIC MICROCYTIC ANAEMIA*

BY

L J WITTS, M D, F R C P

ASSISTANT PHYSICIAN GUY'S HOSPITAL AND EDWARDS CLINICAL RESEARCH FELLOW

In opening a discussion on the classification and treatment of the secondary anaemias one is at once faced with the difficulties of the nomenclature The adjective *secondary* was originally applied to anaemia whose pathology was well understood, in contrast to *primary* anaemias such as pernicious anaemia, whose intrinsic nature was obscure Recent advances in knowledge have done much to obliterate this distinction We now have more information about the etiology of pernicious anaemia than of many anaemias called secondary An additional meaning has, however, become attached to the term secondary In anaemia from simple causes, such as haemorrhage, infection, or toxaemia, the haemoglobin is decreased out of proportion to the red cells, which are often smaller than normal, and the colour index is low When we say that an anaemia is of the secondary type, we usually mean only that the colour index is low It is in this sense that I shall interpret the title of our discussion I hope to show that very little is known of the pathology of many cases of anaemia of low colour index, and that there is a large and coherent group which forms an independent malady, a disease *sui generis*

The adjective *chlorotic* has similarly been so devalorized as to have lost all meaning True chlorosis has practically disappeared There can be few medical men under the age of forty who have ever seen a case of "green sickness" To-day anaemia is uncommon in adolescent

* Read in opening a discussion in the Section of Medicine at the Annual Meeting of the British Medical Association, Eastbourne, 1931

females, and is never associated with a greenish coloration of the skin. On the other hand, anaemia of obscure origin is very common in adult women. Only too often it passes unrecognized, or, if recognized, it is wrongly ascribed to one of the accepted causes of secondary anaemia. It is both meaningless and inaccurate to diagnose these cases as chlorosis.

The haematologist applies the terms *microcytic* or *hypochromic* to all forms of anaemia of low colour index. Although the term hypochromic, which refers to the pallor of the red cells, is more universally accurate than the term microcytic, which refers to their diminished size, I shall prefer to speak of these anaemias of low colour index as microcytic, for reasons of pathology which do not concern us at present. To avoid the associations of such words as secondary or chlorotic, I shall refer to obscure anaemia of low colour index as chronic microcytic anaemia, thus stressing the low colour index and differentiating this form of anaemia from the megalocytic anaemias of which pernicious anaemia is the classical example. Chronic microcytic anaemia constitutes a well-defined malady which is much more common in women than in men and which is susceptible of great improvement on intelligent treatment.

The commonly accepted causes of microcytic or secondary anaemia are haemorrhage, especially from peptic ulcer and tuberculous disease of the intestine, haemorrhoids, and menorrhagia; infection, especially in tuberculosis, acute and subacute rheumatism, and suppuration; new growths; and toxaemias, such as chronic nephritis. In all these conditions the anaemia is merely a symptom of the underlying disease, and it is to the latter that treatment must be directed. Until the cause is removed, haematinic remedies other than transfusion rarely produce any effect. I shall not further refer to these conditions.

The study of a large series of cases of microcytic anaemia reveals two important facts. The first is the great excess of all forms of microcytic anaemia in women. Anni Seppanen (1930)[41] analysed 278 cases of microcytic anaemia which had been admitted to the First Medical Clinic at Helsingfors between 1908 and 1928. During that period 7,706 men and 7,183 women had passed through the clinic. In spite of the preponderance of male admissions, 77 per cent. of the patients with anaemia were women. When all cases of chlorosis, and all in which the anaemia might be attributed to genital haemorrhage, pregnancy, or lactation, had been abstracted, the number of female cases was still 69 per cent. of the total. There was an excess of women in all the groups—haemorrhage, infection, etc.—except malignant disease.

The second important fact is the high proportion of unexplained cases of chronic microcytic anaemia. Seppänen's 278 cases included 30 patients with "chlorosis" and 19 in whom anaemia was either the only symptom or was associated with a functional dyspepsia—that is, 18 per cent unexplained. In an analysis of the cases diagnosed as anaemia at Guy's Hospital in the years 1922 to 1927, I found that there were 183 cases, of which 47 (26 per cent.) were unexplained microcytic anaemia.[56] In the same paper I analysed all blood counts done by Dr. F. A. Knott, the clinical haematologist at Guy's Hospital, in the years 1927 to 1929, and found that there were 137 cases of anaemia, of which 20 (15 per cent.) were unexplained microcytic anaemia.

All these percentages are inaccurate. They probably underestimate the frequency of chronic microcytic anaemia in women. Nevertheless, they serve to emphasize two important facts: (1) that all forms of microcytic anaemia, whether symptomatic of some underlying malady or not, are much more common in the female sex; and (2) that a large fraction of all forms of microcytic anaemia is unexplained, and not due to haemorrhage, infection, toxaemia, or malignant disease. For some years now I have been engaged in a study of this last group, and it has become clear that chronic microcytic anaemia may be an independent disease, with well-defined etiological factors and symptoms, much more frequent in women than in men.

Incidence and Constitutional Type

Defining anaemia as a haemoglobin percentage of less than 75, and limiting my investigations to patients over the age of ten, I have been able to study 117 cases of chronic microcytic anaemia, including "chlorosis," in which none of the accepted causes of anaemia was active. Of these patients 101 (86 per cent.) were women, and for the present I shall confine myself to describing the female cases. The diagram of the age incidence (Fig. 1) shows

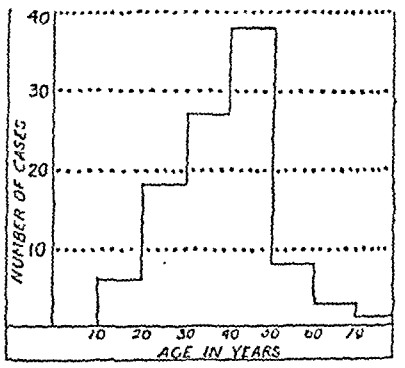

Fig. 1.—Age incidence of chronic microcytic anaemia in women.

a steady increase to a maximum in the years 40 to 50 and then an abrupt decrease. In individual cases which I have followed after the menopause there has been a spontaneous improvement. The age and sex incidence of chronic microcytic anaemia are thus quite different from those of achlorhydria[8 10 23 36] and of pernicious anaemia,[37] which increase in frequency with advancing years, and are said to occur equally in the two sexes. Chronic microcytic anaemia is a disease of the female sex and of the reproductive epoch. True pernicious anaemia is probably more common in men than in women, a fact hitherto concealed by the confusion of simple achlorhydric anaemia and pernicious anaemia.

No social class is picked out, but the women affected often show signs of an asthenic diathesis. This may not be obvious from the external habit of the patient, who in rare instances appears robust, but there is a general constitutional weakness, most evident in the digestive, the reproductive, and the nervous systems. Less commonly the resistance to septic infections is poor, or there is a history of frequent winter coughs or pleurisy, unproductive of physical signs or of *x*-ray changes in the lungs, but suggestive of pulmonary weakness. It is not easy to decide how far such weaknesses are innate and how far they are secondary to the anaemia. Many cases certainly do surprisingly well when the anaemia is corrected, but in the majority there is evidence of debility unrelated to the anaemia. Corroboration of the association of achlorhydria (a symptom of great frequency in chronic microcytic anaemia) with asthenic disturbances, such as the nervous temperament, functional dyspepsia, rheumatoid arthritis, and debility, may be found in the writings of Albu,[1] Warburg and Jorgensen,[2] Wilkinson and Oliver,[3] I have previously discussed the importance of constitutional factors in chronic microcytic anaemia unassociated with achlorhydria.[56]

The debility from which these women suffer may date back to the earliest years of life; they were difficult to rear and had intestinal dyspepsia or "consumption of the bowels" in childhood. The majority are

dyspeptics, even though the gastric secretion may be normal. Nervous instability is present in almost all. It may manifest itself merely as a hyperaesthesia, in which the common pleasures and pains of life produce an excessive response and give rise to undue emotion or insomnia. In other women disabling headaches, pruritus, hysterical phenomena, nervous breakdowns, and even insanity, occur. The reproductive function, which is a measure of the inherent vitality of the organism, is subnormal. Some are the solitary offspring of infertile parents or the children of old age. The catamenia often begin late in life and cease early; the periods are painful. Menstruation is more often scanty than excessive. One-quarter of the patients are single. Complete or relative sterility, miscarriages, and post-partum haemorrhage, are frequent in the married women.

Although the anaemia is intimately linked with the age of reproduction, and is undoubtedly aggravated by pregnancy and by the excessive loss which sometimes marks the establishment and the cessation of menstruation, these factors of themselves seem insufficient to account for its long standing. The physiological anaemia of pregnancy disappears within a few weeks of parturition.[4] The number of pregnancies in the anaemic patients is smaller than in healthy women. An occasional flooding or a post-partum haemorrhage cannot account for anaemia of twenty years' duration. Such loss of blood is trivial compared with that of the transfusion donor, who gives a pint of blood every three months. For these reasons it is clear that, although the strain of menstruation and pregnancy plays a most important part in the development of chronic microcytic anaemia, this is only because of inadequate and subnormal blood formation, which is partly the result of intrinsic constitutional inferiority, and partly of extrinsic factors to be discussed later.

The Anaemia

The anaemia appears to be due to inability to form haemoglobin, in contrast to pernicious anaemia, where the difficulty lies in manufacturing the stroma of the red cells. In a case of average severity a blood count of 3,500,000 red cells per c.mm., haemoglobin 35 per cent., and a colour index of 0.5, are to be expected. Sometimes the total number of red cells is normal and there is a pure haemoglobin deficiency. The red cells are pale, and, in general, the worse the anaemia the lower the colour index. The mean diameter of the red cells is usually diminished and never raised. Reticulocytes are within normal limits and occasional normoblasts are present. The zone of haemolysis with hypotonic saline is widened, but this increased fragility disappears on repair of the anaemia.[15 42] Van den Bergh's reaction is negative, the bilirubin content of the plasma being diminished, as also is the free iron of the plasma.[27 29] Blood platelets are unaffected. The total and differential white count is normal. At times, in the absence of infection or haemorrhage, the Arneth count shows a shift to the left, which disappears on repair of the anaemia. Less often there is a shift to the right, the neutrophils being hypermature.

The spleen is palpable in one-third of all cases, whether achlorhydric or normochlorhydric. It is rarely much more than palpable, but may extend a hand's breadth below the ribs. It completely recedes beneath the costal margin on repair of the anaemia. Excision of the spleen, which should never be performed wittingly, as it is both needless and ineffective, reveals a pure hyperplasia of this organ (McNee's Group IV).[21 43 53] The bone marrow is hyperplastic, with great excess of normoblasts. Hyperplasia gives place to normal maturation of the red cells on successful treatment.[47]

The duration of the anaemia before the patient comes under observation is very variable. Histories are unreliable, on the one hand, because anaemia develops insidiously and is not appreciated till the haemoglobin has fallen below 40 per cent.; on the other hand, because the symptoms of nervous debility or dyspepsia may be indistinguishable from those of anaemia. The history may be brief, the disease beginning spontaneously, or after influenza or confinement. Anaemia may have been continuously present since puberty. Most commonly the patient was treated for anaemia in girlhood, and relapsed again in the thirties. Much must depend on the relative importance of the intrinsic and extrinsic agencies. Achlorhydria, which is the most important etiological factor, is usually secondary to gastritis, and becomes more frequent in the later age groups. The average duration of symptoms is from five to ten years. The natural tendency of the disease is to get progressively worse through the child-bearing period, with exacerbations in pregnancy, and to recover spontaneously after the menopause.

Diet

The diet is often poor in animal protein, but this is not true of all cases by any means, and it is not possible to ascribe the anaemia solely to defective diet. A similar diet is taken by large numbers of people who are not anaemic, and when anaemia results from defective nutrition it is more often megalocytic-aplastic[22] in type than microcytic.[24] Nevertheless, many of these women are ingesting insufficient iron in the food. In some cases of chronic microcytic anaemia, koilonychia, or spoon-shaped depression of the nails, occurs. The nails are so hollow that a drop of water will rest easily on them. On repair of the anaemia the nails grow out in their normal convexity. I have seen koilonychia without anaemia in anorexia nervosa, and it is also described in tuberculosis.[17] It seems to be a sign of defective nutrition.

Intestinal Intoxication and Focal Sepsis

In collecting cases of chronic microcytic anaemia I have been careful to exclude patients with haemorrhage, infection, or toxaemia; but I have included cases attributed to intestinal toxaemia and focal sepsis, as these diagnoses are much abused. In no patient was there any evidence of intestinal toxaemia. Therapeutic measures based on this diagnosis, such as aperients, operation on the colon, or inoculation with faecal or duodenal streptococci, are valueless. Treatment with iron alone cures the anaemia.

Oral sepsis is common in these women, but it plays little part in the inception of the anaemia. Many have had most or all of their teeth extracted without benefit. In only six did this operation seem to have been of value. Careful study of these cases has shown that no improvement in the anaemia can be expected from dental extractions alone unless such signs of septic absorption as fever, leucocytosis, septic rashes, or arthritis are present. Anaemia is very rarely the result of focal sepsis. The streptococci isolated from my cases have nearly always been anhaemolytic. These findings are confirmed by Bullcid,[5] who made a bacteriological study of eight hundred teeth extracted for apical infection, and found that true haemolytic streptococci were very rare, and were usually associated with acute alveolar abscess. I do not wish to deny the existence of anaemia due to anhaemolytic streptococci, but rather to point out that it is rare and usually a febrile ailment.

It must be remembered that the resistance to septic infection is impaired in chronic microcytic anaemia, and it seems that oral sepsis is more often the result than the cause of the debility. The same point has been emphasized by Pemberton[25] and by Douthwaite[11] with regard

to rheumatoid arthritis. In three of my patients, whose teeth had been examined and passed by first-class dentists, rapid infection and decay have subsequently occurred. The same lack of resistance to infection, especially by streptococci, is shown by the skin, and patients of mine have developed infectious eczema, erythema induratum, and chronic paronychia, years after the onset of the anaemia. The lower end of the alimentary canal is not infrequently involved, anal fissures and intertrigo occurring. Infections of the mouth, leading to glossitis, stomatitis, pharyngitis, and dysphagia, and of the stomach, leading to gastritis and achlorhydria, are of such great importance that they must be considered separately.

Achlorhydria

Fractional test meals have been performed in all these 101 women, except in 6, who were unable to swallow the tube on account of dysphagia. In 81 per cent. there was achlorhydria or extreme hypochlorhydria. The details of this achlorhydria have not yet been elucidated, but it appears that while free hydrochloric acid is usually permanently absent, chlorides and pepsin are not diminished to the same degree as in pernicious anaemia and there is not an absolute achylia gastrica. Achlorhydria precedes the anaemia and remains when the anaemia is cured. It is not the result of the anaemia. Gastric lavage and histamine injections fail to provoke the secretion of acid.

What is the cause of this achlorhydria? In many cases it is a hereditary abnormality, as has recently been emphasized by Wilkinson and Brockbank.[30] Achlorhydria alone, achlorhydria plus the pernicious-anaemia-subacute-combined-degeneration syndrome, and achlorhydria plus chronic microcytic anaemia, all run in families. The males are more prone to pernicious anaemia, the females to chronic microcytic anaemia. Gram[16] has brought evidence that it is perhaps not achlorhydria which is inherited, but a vulnerable gastric mucosa, which sooner or later develops gastritis and consequent achlorhydria. In many cases the history is extremely suggestive of gastritis, symptoms dating from an attack of gastric influenza, food-poisoning, or other gastro-intestinal infection. Gastritis may also be the result of oral sepsis. Six of my cases followed gastro-enterostomy.

The close correlation of achlorhydria and anaemia cannot be a matter of chance, and a causal nexus is also clear when anaemia follows an operation on the stomach which produces gastric anacidity. Achlorhydria may produce anaemia in three ways. In the first place, it often causes loss of appetite for non-containing foods such as animal proteins and green vegetables. In the second place, the absorption of iron is probably diminished in the absence of free hydrochloric acid from the stomach.[30] In the third place, it is often associated with other signs of the asthenic diathesis, in which anaemia so readily occurs.

It is very difficult to know the proportion of cases of achlorhydria in which anaemia develops. Hospital statistics are valueless, as they concern only the sick. For this reason my previous computation that among 100 patients with achlorhydria one might expect to find 10 with pernicious anaemia and 20 with microcytic anaemia, is far too high, as Warburg has clearly shown. Pernicious anaemia only develops when the gastric ferments are absent and this true achylia gastrica is much rarer than achlorhydria. Why does achlorhydria not always produce a microcytic anaemia? It seems that a robust constitution and a healthy appetite can overcome this defect. Microcytic anaemia very rarely arises from this cause in males. Recently it has been found, however, that there may be iron deficiency in pernicious anaemia also.[43]

After operations on the stomach severe anaemia develops more frequently in women than in men.[44] In my [illegible] women patients with anaemia after gastro-enterostomy there were well-marked signs of an asthenic diathesis. In two no ulcer had ever been demonstrated, the operation having been performed for gastroptosis; one had been treated for anaemia in girlhood, one had had dysphagia before the operation, and the fifth had had hysterical paraplegia ever since a haematemesis fifteen years before the operation. For all these reasons it appears that achlorhydria is rarely sufficient to produce microcytic anaemia unless the basic constitution I have described is present.

Glossitis and Dysphagia

In 1851 Moeller described six cases of chronic excoriation of the tongue in middle-aged women. A similar condition was noted in pernicious anaemia by William Hunter in 1889. About this Moellerian or Hunterian glossitis there has grown up an extensive literature, which has been reviewed by Heyn[18] and by Lewis.[23] The glossitis is a well-defined malady, but it occurs in a number of diseases of a nutritional or metabolic nature, and though usually associated with gastric anacidity, it may be found in cases of anaemia or malnutrition, tropical or non-tropical, in which free HCl is secreted in normal concentration.

This type of glossitis is present in about half of the cases of chronic microcytic anaemia. It is often painless and unknown to the patient. In the active stages the tongue is reddened and excoriated; vesicles may appear and break down to form shallow ulcers. In the chronic and quiescent stages the filiform papillae are destroyed, leaving a smooth, bald tongue. Inflammatory changes in the mouth are not limited to the tongue. The inflammation may spread to the buccal mucosa and to the corners of the mouth and lips, conditions known as stomatitis and perlèche. Passing backwards to the pharynx it produces huskiness and, when the nerve terminals in the pharynx are involved, a most troublesome dysphagia, which may be the presenting symptom.

In my experience pharyngitis and dysphagia never occur without glossitis, and stomatitis rarely. All are more frequent in achlorhydria, but may accompany normal gastric secretion. When the gastric juice is normal, recurrent erythematous and herpetiform eruptions of the mouth and tongue, which subside without residue, are more frequent. The cause of these mouth changes is much debated. They seem to be initiated most commonly by streptococci.[2 20 40 42] In some cases monilia are found. The aphthous eruptions may be due to the virus of herpes simplex, like those of childhood.[33] The fundamental cause is a peculiar lack of tissue resistance to organisms in the mouth, resulting most frequently from achlorhydria but also from other disturbances of nutrition.

Oedema and Angina

Several of my patients have had slight oedema. I have never seen gross oedema, but the literature contains reports of cases of achlorhydria and anaemia, in which there was general anasarca.[12 21 38] Elwyn[12] refers to other cases of achlorhydria with anasarca, in which there was no anaemia or where complications sufficient to account for the anaemia were present. The oedema in these cases, like the anaemia, is due to impaired nutrition, and is comparable with war nutritional oedema.[29]

True anginal pain on exertion, which disappeared on repair of the anaemia, was present in two of my cases. Angina from poor quality of blood is therefore not limited to pernicious anaemia.

Classification

In a series of papers[23 35 36] I have discussed chronic microcytic anaemia in women in three subgroups, but it may

be clearly understood that the age incidence, the anaemia, and the constitutional background are identical throughout, and that this is merely a convenient symptomatic subdivision. The disease is a single entity.

Simple Achlorhydric Anaemia.—This is the largest group, comprising 69 of the 101 cases. In brief summary, it is a disease of middle-aged women, all of whom prove to have achlorhydria or extreme hypochlorhydria. The disease is chronic and shows little tendency to spontaneous recovery until after the menopause. Medical advice is sought either for symptoms of anaemia or because of dyspepsia. The pallor is often striking, but it has not the lemon-yellow tinge of pernicious anaemia, and van den Bergh's reaction is negative. The nails are often spoon-shaped. Glossitis may be present, and not infrequently the spleen is palpable. There may be paraesthesia of the hands and feet but there is no sub-acute combined degeneration of the cord. The anaemia is of low colour index, haemoglobin being disproportionately reduced and the average diameter of the red cells diminished. White cells and platelets are normal; megaloblasts never appear. At biopsy or post-mortem the bone marrow is found to be hyperplastic, normoblasts are much increased in numbers, but there are no megaloblasts.

Dysphagia and Anaemia.—This group comprises 13 of the 101 cases. The inflammatory changes in the mouth spread backward to the pharynx, destroying the nerve terminals which initiate the swallowing reflex and giving rise to the cardinal symptom of dysphagia. Achlorhydria is frequent—in five out of seven patients (Witts);[31] eight out of ten patients (Moersch and Conner);[32] and in five out of five patients (Graham and Johnson);[33] Cameron,[4] however, found free hydrochloric acid "in all of his 25 patients on whom he was able to pass a tube." The other signs and symptoms are identical with those of simple achlorhydric anaemia. Their close relationship is shown by the occurrence in my series of a mother of 44 with dysphagia and anaemia, and her daughter of 23 with simple achlorhydric anaemia.

Chlorosis and Late Chlorosis (Visceroptosis and Anaemia).—In the remaining 19 of the 101 cases neither achlorhydria nor dysphagia was present, and glossitis was much milder. The anaemia and other symptoms were identical, but the group was distinguished by pronounced stigmata of the asthenic diathesis, all being of the chronic invalid type, as described by Bedingfield.[3]

Diagnosis

Anaemia is a symptom of many disorders, and it is of paramount importance not to diagnose an idiopathic anaemia without the most careful examination of the patient. Malignant disease often presents itself as an obscure anaemia and must be considered in all cases. The occult blood test on the faeces should be a routine. In women particular inquiry should be made for excessive menstrual loss. The case should never be long confused with pernicious anaemia: the low colour index and negative van den Bergh reaction are incompatible with this diagnosis, as also is the failure to respond to treatment by liver or stomach. In the rare disease aplastic anaemia, the colour index is high, white cells and platelets are diminished, necrotic ulcerations occur, and there is no response to iron.

Much difficulty may be presented by the diagnosis from splenic anaemia, as achlorhydria, anaemia, leucopenia, and splenomegaly occur in both diseases. Cases of chronic microcytic anaemia are frequently diagnosed as splenic anaemia, and I have known several women refuse operation advised on this diagnosis and return later with a spleen no longer palpable. A spleen below the umbilicus is not likely to be due to chronic microcytic anaemia. If there is a small spleen and anaemia of low colour index, if there is no history of jaundice or haematemesis, if skin pigmentation, clubbing of the fingers, and signs of liver damage such as enlarged veins, positive van den Bergh reaction, and impaired levulose tolerance are absent, the case should always first be thoroughly treated with iron, when the anaemia and the spleen will disappear if the correct diagnosis is chronic microcytic anaemia.

Infective endocarditis and myxoedema are other differential diagnoses which have offered difficulty. More commonly anaemia is overlooked, and the case is diagnosed as hysteria, debility, or functional dyspepsia. These maladies may indeed be present, but they will improve much more satisfactorily when the blood is restored to normal.

Prognosis and Treatment

The prognosis as regards life is good. Kaznelson[21] has described a fatal case, but this must be a rare event. Transition to pernicious anaemia is also very uncommon. Only two of my patients have developed pernicious anaemia, though they have been watched for intervals extending up to nine years. The risk is greater when there is a family history of pernicious anaemia. The prognosis of the anaemia is not good. Relapse is common, especially after incomplete treatment.

The anaemia must be treated with iron by mouth. Small doses and injections are useless. The minimum effective dose of iron and ammonium citrate is 60 grains a day, and of Blaud's pill 30 grains; I prefer 90 grains and 40 grains respectively. I have recently reviewed the results of iron treatment in detail,[37] but would emphasize that effective treatment nearly always takes three months, while it may need a year. Treatment must be continued till the haemoglobin is raised to 80 per cent., for relapse is then much less frequent. The results of vigorous treatment with iron are uniformly good. Failure means either a wrong diagnosis, too small a dose, or a complication such as an active septic focus. Large doses of iron are well tolerated and improve digestion. Few facts in medicine are so unanimously believed by the expert, so strongly backed by evidence, and so little known to the profession, as the absolute necessity of very large doses of iron in the treatment of these chronic anaemias.

Transfusion is temporarily effective, but soon followed by relapse. Liver, liver extract, liver ash, desiccated stomach, and hydrochloric acid, are all without effect on the anaemia.[34 35] Copper plays no part in the action of the large doses of iron. An analysis of the preparations of iron I have used revealed between 3 and 4 milligrams of copper per kilo, which would give only 1/100 milligram of copper per day, or less than the food contains.

Anaemic patients should be confined to bed. The diet should be varied, and should include red meat, liver, or kidney every day. Foci of sepsis should be eliminated, as they delay the response to iron, and keep up the inflammatory changes in the mouth and throat. Glossitis, pharyngitis, and stomatitis usually improve on repair of the anaemia. In some instances they are most intractable. Elimination of septic foci, liver, hydrochloric acid, concentrates of all the known vitamins, have all proved ineffective in these stubborn cases. I am now trying desiccated stomach on the suggestion of Dr. J. F. Wilkinson, who has found that it always cures the glossitis of pernicious anaemia.[47] Dysphagia is treated by the passage of Hurst's mercury tube.

Menorrhagia may be a very troublesome complication. In certain instances, as soon as the haemoglobin has been raised by iron to about 70 per cent., a previous amenorrhoea gives place to menorrhagia. The patient must

remain in bed throughout the period, omitting iron, and taking instead about 100 grains of calcium lactate a day, supported if necessary by injections of cotarnine hydrochloride. After a few months the periods settle down to a normal amount and duration. Menorrhagia is common again about the climacteric. Although not the prime cause of the anaemia, for the patient has previously suffered from anaemia and scanty menstruation, it may nullify all haematinic therapy. It is unwise to wait too long for a natural menopause, as this may condemn the patient to years of invalidism. Treatment by *x*-ray or subtotal hysterectomy should be recommended early; the results are extremely good.

Anaemia in Men

Little can be said about anaemia in men. It is usually of short history, responds rapidly to large doses of iron, and rarely relapses. The cases are equally divided into a group in early life with normal gastric secretion and no symptom except anaemia,[19 54] and a group in later life with simple achlorhydric anaemia. It may be noted in conclusion that although simple achlorhydric anaemia occurs with greatest frequency in women in the reproductive period, a small but important number of cases occur in old people of either sex.[10]

Summary

1 Chronic microcytic anaemia, for which none of the usual causes of secondary anaemia can be found, occurs with considerable frequency in women of reproductive age The women affected are generally of asthenic constitution, and achlorhydria is present in 80 per cent.

2 The anaemia is chronic and shows little or no tendency to improve until after the menopause, when it may disappear spontaneously.

3 The spleen is palpable in one-third of the cases, but recedes beneath the costal margin on repair of the anaemia.

4 Superficial glossitis, indistinguishable from the sore tongue of pernicious anaemia, is present in one-half of the cases Stomatitis also occurs. In about 15 per cent. the inflammation spreads to the pharynx, producing dysphagia, which may be the presenting symptom.

5 Treatment is simple and effective. All cases respond to iron, provided it is given by the mouth in large doses for an adequate period of time. Liver is of no value. Owing to the risk of relapse, it is advisable to continue a small maintenance dose of iron after the anaemia has been cured.

Note on the Literature

I have reviewed the literature in previous papers.[53 54 55 56 57] Subsequent descriptions of chronic microcytic anaemia are listed below [13 26 27 32 46] I had previously overlooked West's paper,[48] which was published under Dr. A. F. Hurst's direction in 1928, and which must be one of the earliest English descriptions of uncomplicated simple achlorhydric anaemia. Naegeli[54] gives an admirable short account of these anaemias in the last edition of his textbook, regarding them as variants of chlorosis and stressing the constitutional basis. I have to thank Professor A W M Ellis, of the London Hospital, and the physicians of Guy's Hospital, for the opportunity of studying patients under their care I am indebted to the members of the Will Edmonds Committee for Clinical Research, and especially to Dr. A. F. Hurst, for much advice, encouragement, and assistance.

SIMPLE ACHLORHYDRIC ANAEMIA TREATED BY IRON

BY

D. C. HARE, M.D, M R C P.

PHYSICIAN, ROYAL FREE HOSPITAL

Simple achlorhydric anaemia has emerged slowly as a definite entity from among the group of secondary anaemias, and it is remarkable that general recognition o the condition has been so long delayed. A valuable pape on the subject was published by L. J. Witts[1] in 1930 with an analysis of fifty cases and full references to the literature; more recently prominence was given to the subject in a discussion on iron therapy at the Roya Society of Medicine [2]

The subject is of importance and interest for th following reasons. (*a*) There is reason to believe that th anaemia is a modern disease; a study of the literature o blood diseases of the past century reveals no clinic description of the present type. It somewhat resembl chlorosis, but can be sharply defined from it. (*b*) Th

logy of the condition is of great importance. The emia is associated with a chronic gastritis, to which achlorhydria may be secondary, as emphasized by T. Davies.[2] (c) The condition is not uncommon in men in the fourth and fifth decades of life, but it appears probable that the majority of the patients go relieved, being insufficiently dosed with iron, or treated with liver and stomach extracts which have no curative effect.

Description of the Disease

From the clinical aspect it may be described in general terms as an anaemia of insidious origin and great chronicity, affecting females almost exclusively, and developing between the ages of 30 and 40 years. There is usually no close association with haemorrhage or sepsis, but it is frequently accompanied by gastro-intestinal lesions, such as stomatitis, fissures at the angles of the mouth, *glossitis, pharyngitis, gastritis,* and occasionally colitis, producing the symptom-group of the Plummer-Vinson syndrome. Palpable enlargement of the spleen is sometimes present; other symptoms and physical signs are such as are secondary to the anaemia—breathlessness, palpitations, giddy and fainting attacks, and cardiac dilatation.

From the laboratory aspect the condition is an anaemia of chlorotic type—a haemoglobinaemia. There is no evidence of blood destruction within the tissues. The red cell count is often but little reduced, and may be normal or even before intensive treatment; during treatment an erythrocytosis commonly develops. The cells show anisocytosis with many microcytes at first, but appear to be of normal average size during a remission. The colour index may be extremely low during the untreated phase, and tends to remain subnormal throughout. The fractional test meal shows achlorhydria or hypochlorhydria; there is usually excess of mucus.

Differential Diagnosis

The differential diagnosis of chlorosis and simple achlorhydric anaemia is of interest. The blood picture of the two anaemias is practically identical; but a comprehensive article on chlorosis by Sir Clifford Allbutt[3] in 1898 gives a description of a clinical type which can be made to include simple achlorhydric anaemia, nor can it be recognized under any other heading. It is unbelievable that anaemia of such definite clinical characteristics could have escaped the acute observers of the end of the last century. Chlorosis was then so common that, to quote from Allbutt, "It was well known in every consulting room, public or private"; it was "no respecter of race, rank, or fortune"; "a disease of country and of town alike"; and so predominantly a disease of virgins that Lloyd Jones, who had made a special study of the subject, is quoted as saying that in twenty years of practice he had only seen two cases in married women, and both of those were domestic servants who had never borne children. Some cases of chlorosis are indeed described as persisting into middle life, with frequent relapses; but there is no doubt that the simple achlorhydric anaemia of the present day is not a persistent chlorosis. The age of onset of simple achlorhydric anaemia in Witts's series is in the fourth or fifth decade in 70 per cent., and his youngest patient is 22 years old. *The married women in the present series have all borne children* (six cases, with twenty-five children). A normal or good gastric secretion is reported to be present in chlorosis; this is mentioned by Allbutt and by more recent writers. The resemblances between the two diseases are (*a*) the blood picture, (*b*) the sex incidence, (*c*) the tendency to relapses, and (*d*) the cure or permanent remission which follows continued treatment by large doses of iron. The differences lie in (*a*) the age incidence, (*b*) the relation to sex activity and fecundity, and (*c*) the gastric secretions. Lastly, there is the striking fact that during the last thirty to forty years chlorosis has been disappearing, and a formerly unknown type of anaemia has appeared.

Therapeutics

The disease appears to be one of severe iron deficiency, and only a moderate increase of haemoglobin is found after administration of iron preparations in the official pharmacopoeial doses. In Case II, after eight months' treatment, haemoglobin was 56 per cent. In Case I, after four months, haemoglobin was 68 per cent., but the response was probably assisted by a blood transfusion at the beginning of the period; three months later the haemoglobin had fallen to 50 per cent. The following treatments were given without apparent benefit. *Injections of iron and ammonium citrate up to 1½ grains daily.* Arsenic was given in Cases II and III. Liver, half a pound daily for considerable periods, in Cases I, II, III, and IV. Hydrochloric acid was given to most of the patients. Stomach lavage was performed daily with hydrogen peroxide in Cases III and IV, for periods of seventeen days and six weeks respectively. Blood transfusions were given to two patients. In Case I, two transfusions at intervals of nine months were followed by temporary improvement; in Case IV one transfusion was done. The improvement appears to last from two to three months.

As will be seen from the records below, in Cases I to V the patients had been under observation and treatment for a considerable time before massive iron dosage was given. Some had improved and relapsed again, but in none had the blood condition reached normal; the haemoglobin was still below 60 per cent. in all the cases when massive iron dosage was begun. The rise in the months following was so striking that it is difficult to believe that it is to be attributed to the cumulative effect of the previous treatments. In Case VI there had been no previous treatment, and the results were equally impressive. In Case IV smaller doses were given than in any of the other cases, and the maximum rise of haemoglobin was the lowest shown. In Case IX no regular treatment was given; this demonstrates the fact that the anaemia shows no tendency to spontaneous remission. The results are uniform except in Case VIII; the complete failure of haemoglobin response to treatment suggests that the case belongs to a different category, though the clinical findings appear similar. The tendency to relapse is shown by Case III, in which no treatment was given for ten months, when the haemoglobin was found to have fallen from 110 to 77 per cent., although the patient had been well throughout, and was not aware of any deterioration of her health.

The Iron Preparation and Dosage.—According to the practice of Witts and others, the preparation used in most of the cases has been the iron and ammonium citrate in doses of 90 grains daily, increased to 120 grains and diminished to 60 grains in single instances. Pilula ferri was given in one case up to a dose of 90 grains daily for six weeks; the result did not appear to be so good as in cases treated with the scale preparation. No contra-indication to these large doses has been met with; some of the patients *complain of flatulence, but this is a frequent* complaint in this condition apart from the taking of iron; others complain of constipation, but it is not severe, and is easily counteracted by mild aperients. A full account of the value of different forms of iron is given by L. J. Witts.[2]

The Changes in the Blood under Treatment.—There is a tendency in these cases to a high initial red cell count,

with the development of an erythrocytosis under treatment. Five million per c.mm. being taken as a normal maximum (though this is considered high for women by some workers), three cases showed an erythrocytosis actually before treatment with massive doses of iron—Cases II, IV, and VI; and two (Cases V and VII) had counts of a normal figure. In all the cases (except Cases III and VI) iron had been given in small doses before the massive doses were begun. Smaller doses may be sufficient to stimulate red cell formation, though inadequate for haemoglobin manufacture. The erythrocytosis was more than a transitory feature, persisting in two cases for more than thirteen months; in one case it reached the maximum recorded as early as six weeks. During the period of haemoglobinaemia the red cells show much anisocytosis and poikilocytosis, with many microcytes; but during a remission the cells are of normal average diameter. The haemoglobin increase that follows massive doses of iron may begin within the first two or three weeks (an increase of 25 per cent. in three weeks occurred in Case III), but the maximum increase lags behind the maximum red cell count for three or four months. The colour index, which is extremely low before treatment, has not been recorded as unity in any one of these cases, even after long treatment; the highest figure was 0.96 in Case I. The white cells show no change either in the total or differential counts.

The following are the clinical histories and blood records of nine cases. Six of these are typical of the condition, in which complete remissions were obtained under treatment. Most of the cases are still under observation.

Case I

A spinster, aged 41, had severe anaemia in 1918 at the age of 29, she had probably had some degree of anaemia for years previously. All her life she had suffered from neglected constipation, with a tendency to slight haemorrhages from the bowel. She was treated for "colitis" in 1920 with appendicostomy—closed in a few weeks. Bleeding piles removed in 1925. Transfusions for anaemia in 1927 and 1928. Slight recurrent febrile attacks with colitis during 1928 and 1929; symptoms were abdominal pain, flatulence, glossitis, and dysphagia. Menses fairly regular, no excessive loss.

Examination in August, 1929.—Nutrition fair, fissures at corners of mouth, papillae of tongue atrophied, tongue sore, pain and difficulty in swallowing, spleen not felt, liver normal. Sigmoidoscopy—no ulceration seen. Large uterine fibroid, no haemorrhage. Wassermann reaction negative. Test meal—secretion obtained by vomiting one hour after usual gruel meal—nearly pure mucus, complete achlorhydria, low chlorides. In hospital five months with continued low fever; treatment with large doses of anti-dysenteric serum caused high temperature reaction, and was followed by improvement in bowel symptoms and normal temperature. No improvement in blood condition during four months following; immediate improvement with massive iron, no relapse in anaemia or bowel symptoms after fifteen months. Still takes iron regularly.

Blood Records

		R.B.C.	Hb	C.I.
		Millions	Per cent	
8/6/27	Before first blood transfusion	2.52	36	0.66
3/3/28	Before second blood transfusion	4.47	32	0.35
9/8/28	After five months liq. ferri perchlor.	5.13	68	0.6
9/10/28	Liver 6 oz. and HCl and Fe	4.81	51	0.5
7/10/27	After two months' hospital treatment for colitis	5.28	38	0.36
16/4/30	Before massive iron	5.5	44	0.4
5/5/30	After nineteen days' treatment	5.8	58	0.5
8/9/30	Iron continued	6.2	96	0.7
5/12/30	Ditto	5.65	105	0.94
4/5/31	Iron for two weeks each month since March 30th	5.9	98	0.8

Case II

A married woman, aged 49. Four children, youngest 16. "Anaemia" since 14 years old; "heart trouble" since the war; for past two years breathless, choking, and giddy on exertion, but still keeps house for family of eight. Appetite very poor, occasional indigestion. Menses always rather profuse, and during first six months of 1929 loss more severe, but no period for ten weeks before admission. First seen August, 1929. Thin, tongue smooth, not sore, very septic teeth, heart dilated, no valvular disease, spleen not felt, liver normal. Fractional meal—much mucus, complete achlorhydria.

Blood Records

1/4/30	Fe. am. cit., 60 grains for four days	6.2	56	0.5
25/5/30	Ditto 90 grains from 24/4/30	6.3	78	0.6
21/11/30	Fe omitted for time, but regular since October 2nd	5.76	97	0.85
22/3/31	Fe regularly	—	135	—

Case III

Married woman, aged 43. Three children, youngest 6 months. Severe haemorrhage with first confinement, but no abnormal loss with second and third; "anaemia" with each. First seen February, 1930. Thin, spleen not felt. Wassermann reaction strongly positive. Fractional meal—much mucus, complete achlorhydria. Novarsenobillon injections (total 0.8 gram) given; treatment stopped on finding urobilin in the urine, and quinine-iodo-bismuth given. No improvement in anaemia could be ascribed to these drugs. Daily stomach lavage given for seventeen days, no concurrent improvement. Massive iron given, followed by rapid improvement.

Blood Records

		R.B.C.	Hb	C.I.
		Millions	Per cent	
10/29	Soon after confinement	1.85	22	0.6
17/3/30	Before massive iron	4.23	23	0.35
18/2/30	After five months' iron	6.31	110	0.8
12/6/31	Iron omitted ten months	4.73	77	0.8

Case IV

Married woman, aged 48. Three children, youngest 17. In 1928 first gastric symptoms; in 1929 attack of "gastric influenza"—that is, abdominal pain with vomiting and fever; first seen three months later with complaints of flatulence and palpitations. Appetite fair, digestion usually good; diet includes meat and green vegetables. Menses normal, at six weeks' interval. Spleen not felt. Wassermann reaction negative. Fractional meal—resting juice some excess of mucus and pus, complete achlorhydria. Later, severe haemorrhage from uterine polyp, which was removed by operation; no further haemorrhage.

Blood Records

		R.B.C.	Hb	C.I.
		Millions	Per cent	
7/5/29	Before haemorrhage	4.89	72	0.31
7/11/29	After haemorrhage	3.5	20	0.28
5/12/29	Three weeks after blood transfusion	5.44	46	0.42
17/3/30	Before massive iron	5.9	50	0.5
28/4/30	After five weeks' iron	6.3	75	0.6
8/5/31	After thirteen months' iron	5.5	88	0.8

N.B.—Dose of iron 60 grains daily except for very short periods of 90 grains. Patient did not take larger dose well.

Case V

Married woman, aged 41. Four children, youngest 9. When 33 years old was sent to sanatorium for tuberculosis; no symptoms since. Appetite poor, flatulence slight, diet ordinary, including meat and green vegetables. Menorrhagia treated for two to three years, but menses natural for past six months. Thin, spleen not felt. Fractional meal—much mucus, complete achlorhydria, chlorides low. Very slight response to treatment with ordinary hospital iron mixtures; good response to massive iron (see Table below).

Case VI

Married woman, aged 35. Three children—two living, aged 12 and 10, one died at birth seven years ago. Four years ago "gastric influenza," details forgotten. Menses normal, but recently at two to three weeks' interval only. Duration of present symptoms four months; complains of "stomach pains and flatulence which keep her awake." Appetite good, takes ordinary food. No previous attack, never sore tongue. Spleen definitely palpable. Wassermann reaction negative. Fractional meal—complete achlorhydria, no excess of mucus. No previous treatments. Good response to massive iron (see Table).

Table showing Response to Massive Iron Dosage

Case No.	Treatment before Massive Iron	Blood Records: Minimum at any Period		Immediately before Treatment		Maximum during Treatment	
		Hb	R.B.C.	Hb	R.B.C.	Hb	R.B.C.
1	Fe, liver, transfusion	22	3·6	44	4·4	105	6·2
2	Fe eight months	23	4·13	56	6·2	105	6·5
3	Liver, N.A.B.	22	1·85	30	4·0	110	6·33
4	Fe, As, liver	20	3·5	50	5·95	88	6·3
5	Fe six months	35	4·85	44	5·0	94	6·5
6	None	—	—	60	5·9	110	6·75

Fe = Iron in ordinary doses by mouth or subcutaneous injection.
Hb = Haemoglobin per cent., by Haldane's method.
R.B.C. = Red blood cells in millions per c.mm.
Massive iron = Fe. ammon. cit. 90 grains daily, except in Cases iv and v. In Case iv 60 grains daily were given, in Case v 90 grains—but irregularly.

The minimum and maximum records only are given in the table, numerous other examinations were made, but not at sufficiently regular intervals to determine accurately the length of time required to obtain the maximum response to treatment. From the records, however, it is clear that the rise of haemoglobin to its maximum is much slower than that of the red cells. The red cell maximum was obtained after periods of treatment varying from six weeks to seven months, with an average for the six cases of four months; the haemoglobin maximum was recorded after periods varying from five to ten months, with an average of 7.3 months.

The following two cases are reported, one as showing an incomplete response after five months' treatment, and the other as failing to show any haemoglobin response at all. Both were treated as out-patients, and the cause of failure could not be fully investigated.

Case VII

Spinster aged 29. Not well since arthritis when 27 years old. Menses irregular, and scanty for five months. Fainting and giddiness; appetite capricious; eats very little meat; nausea and vomiting occasionally. On admission, nutrition fair, spleen not felt. Wassermann reaction negative. No arthritis, ten carious teeth extracted in hospital. Fractional meal—much mucus, hypochlorhydria.

Blood Records

		R.B.C.	Hb	C.I.
		Millions	Per cent.	
23.3.30	Before treatment	4·75	38	0·4
29.4.30	After four weeks pill. ferri rep. to 90 grains daily	4·83	53	0·6
1.10.30	After five months fe. ammon. cit. 90 grains daily	4·82	80	0·8

Case VIII

Married woman, aged 40. One child, aged 17. Anaemia after severe uterine haemorrhage in 1927; ill with diarrhoea and vomiting for one month, in October, 1929. Menses usually regular and scanty. Long history of "gastritis"; haematemesis twenty years ago. Tongue sometimes sore, and easily irritated by condiments; corners of mouth cracked and sore. Often suffers from palpitation. No history of rheumatic fever. On examination nutrition fair, spleen not felt. Heart, well compensated mitral stenosis with regurgitation, lesion of moderate severity. Wassermann reaction negative. Fractional meal—no excess of mucus, hypochlorhydria. Same report one year later.

Blood Records

		R.B.C.	Hb	C.I.
		Millions	Per cent.	
12.5.30	Before treatment	5·0	32	0·3
5.6.30	Fe. ammon. cit. grains 90 per day	—	—	—
13.7.30	After six weeks' treatment	3·9	23	0·4
5.12.30	Taking Fe regularly	4·85	44	0·45
23.5.31	Ditto	5·05	35	0·35

This patient constantly maintains that she feels very well, and has refused admission to hospital; but there is no reason to doubt that she takes the dose of iron prescribed. The failure of the haemoglobin response is, however, complete.

Case IX

Married woman, aged 35. Seven children, eldest 14. First seen January, 1927. History of post partum haemorrhage with fifth confinement, and anaemia since. "Gastritis" at 14 years of age. A little vomiting with pregnancies, and one slight haematemesis, a little bleeding from piles occasionally; no menorrhagia, no excessive haemorrhage with later confinements. Is very breathless, and has giddy and fainting attacks during pregnancies. Examination—nutrition fair, liver and spleen not felt. Wassermann reaction negative. Fractional meal—much excess of mucus, complete achlorhydria.

In three and a half years of observation the highest haemoglobin record in this patient was 56 per cent., shortly after a blood transfusion; two further pregnancies occurred during that period. Massive iron was ordered during 1930, but the treatment was not continued, as the patient attends very irregularly, and always says that she feels "much better."

Blood Records

		R.B.C.	Hb	C.I.
		Millions	Per cent.	
4.1.27	Seven months pregnant	4·5	40	0·44
11.3.27	Four weeks after confinement and blood transfusion	4·44	56	0·6
7.10.29	—	3·19	20	0·3
12.9.30	Fourteen weeks pregnant, feeling well	4·52	40	0·44

I am indebted to Dr. D. M. Vaux for the blood examinations, and to Dr. E. M. Martland for the test meal examinations.

INFARCTION OF THE MYOCARDIUM*

BY

W. G. BARNARD, M.R.C.P.

DEPARTMENT OF HISTOLOGY, LONDON COUNTY COUNCIL

Infarction of the myocardium is the commonest cause of sudden death in the elderly, and so is of particular interest to pathologists, medico-legal experts, and clinicians. It will be convenient to describe and discuss the changes under the following heads: (1) no myocardial change, death occurring so suddenly that there has not been time for anatomical change; (2) visible infarction—*myomalacia cordis*; (3) slower progressive closure of artery, producing myofibrosis; (4) mixtures of these.

First, then, when a coronary artery is occluded the patient may die within a minute or two, and at post-mortem the myocardium may appear normal. The cause of this sudden death is not yet clearly understood. It is certainly too sudden to be accounted for by lack of oxygen supply to the muscle; for if this were the explanation a more gradual death would be expected; and, further, it has been shown under experimental conditions that the myocardium can continue contracting for some time without an arterial blood supply.

Ligature of the Coronary Artery

The first experimental ligature of a coronary artery was performed by Chirac in 1698. Since then Erichsen (1842), Bezold and Breyman (1867), Samuelson (1881), Cohnheim (1881), and Porter (1896), have all ligatured coronary arteries under various experimental conditions, and have all found that the heart stops beating within one or two minutes after ligature of a main branch of the coronary artery. With better technique Miller and Mathews (1909) and Smith (1918) found that only a few of the dogs died if two main branches were ligatured. When a heart stopped beating within a few minutes of the coronary occlusion they observed that it did so because the left ventricle went into fibrillation, became dilated, and stopped beating; the rest of the heart became dilated, and also stopped. The experimental evidence, therefore, goes to show that the cause of sudden death in coronary occlusion is an upset in the rhythmical contraction of the myocardium of the left ventricle, and is not the failure of an exhausted muscle deprived of its blood supply. It is important that this should be quite clearly grasped, because it partly explains why there is neither macroscopical nor microscopical evidence of change in the myocardium affected in these cases. The other part of the explanation is that we only recognize infarcts by the autolytic changes in them, and these take time to develop. Since there will be no change in the myocardium, the pathological diagnosis in this type of sudden death will depend on the finding of an occluded coronary artery.

Infarction

If the patient survives the occlusion the extent of the changes shown by the myocardium will depend on the size of the vessel affected and on the condition of the other artery; the character of the changes will be the same, and are those of infarction, organization, and fibrosis.

It is convenient to classify the infarcts as large or small under the terms "massive" and "molecular" necrosis, and a description of a massive necrosis or large infarct of the myocardium will be given first. Its commonest situation is that part of the left ventricle which lies immediately beneath the endocardium. The earliest microscopic change consists in the affected part becoming a little swollen, glassy, and reddish-purple. This very early change is seldom seen, because patients either die within a minute or so of the occlusion of their coronary artery (in which case no change is discernible), or they live until the later changes have developed. Later, the infarct exhibits the usual appearance of an anaemic infarct anywhere else—that is to say, it is opaque, pale yellow, or clay-coloured. The dead tissue may give way at this stage and the patient die of haemopericardium. In the periphery of the infarcted area numerous polymorphs collect, and an active granulation tissue develops, which separates the normal from the infarcted myocardium. A heart the seat of such an infarct now presents the following features: immediately beneath the endocardium there is an opaque clay-coloured zone, separated from the normal myocardium by a band of grey gelatinous tissue, and in some cases, particularly if the necrosis reaches the pericardium, there is local, or even general, pericarditis. Microscopically the dead muscle is distinguished from the living by being swollen and glassy, while the nuclei have either disappeared or are in various stages of degeneration. In the periphery of the dead muscle, and infiltrating it, is the granulation tissue. The cross striations of the myocardium may persist for some time after it is dead.

Next, the dead part becomes autolysed, infiltrated by polymorphs, and gradually resorbed; the granulation tissue becomes less and less cellular, and the fibroblasts more mature, until, finally, there is a dense fibrous scar representing the infarct—a scar produced by the granulation tissue which has removed the dead myocardium. This fibrous tissue will tend to stretch under the intracardiac pressure, and if it covers a wide enough area an aneurysm results.

The pericarditis may also organize, producing fibrosis varying in extent from a local patch of thickening to local or obliterative fibrous pericardial adhesions.

Rupture

As has been mentioned, the heart may rupture through an infarcted area, or an aneurysm may rupture—neither is very common in ordinary hospital practice.

Molecular Necrosis

In those hearts in which multiple or single patches of fibrosis are found there is no reason to suppose that the process of killing and removing the myocardium differs materially from that described for the massive infarcts.

The Coronary Arteries

There are only two common causes of occlusion of a coronary artery: one, the degeneration of its wall with or without thrombus, and the other, syphilitic aortitis, which sometimes closes the orifices of the coronary arteries. Of the innumerable uncommon causes embolus is often mentioned, but this is a rare cause; when it does occur it is usually associated with valvular disease of the heart.

Atheroma of the coronary arteries is by far the commonest cause of cardiac infarction, and as this term is seldom used with the same meaning by different authors it will be advisable to indicate that it is employed here in the sense in which Turnbull uses it in his classical paper on arterial structure. That is to say, it is a degeneration characterized by the accumulation of debris, which is at first fatty, and, later, impregnated by calcium, and which is practically confined to the intima. For simplicity of description I have included under "atheroma" hypertrophy of the intima as well as actual degeneration. Atheroma occurs most commonly in localized patches of intimal hypertrophy, and this combination may close the lumen of the coronary artery, or a thrombus may be deposited on its roughened surface and complete the

* Paper read to the Section of Pathology at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

closure. On examination of a heart in the post-mortem room the ordinary method of opening the coronary arteries with scissors sometimes fails to demonstrate the block. If there is a small thrombus covering an ulcerated plaque it is easily removed or pushed on and squashed by the point of the scissors, and is so missed. A more satisfactory method consists in making transverse incisions with a knife, starting near the origin of the coronary arteries and working along their course.

When cardiac infarction is caused by syphilis it is due to the involvement of the orifices of the coronary arteries by syphilitic aortitis, and, apart from gummata of the myocardium, I have not seen syphilitic arteritis of the coronary arteries, except at their origins, and then only in syphilitic aortitis.

As a rule, cardiac infarction occurs at an earlier age when caused by syphilis than when caused by atheroma. Since 1924 I have had thirty-five cases due to atheroma, with an average age of 61; during the same period four were due to syphilis; their ages were 50, 51, 28, and 47. Here it may be remarked that syphilitic aortitis may be present with cardiac infarction in cases in which the infarct is due to atheroma of a coronary artery and not to syphilitic aortitis.

AN EPIDEMIC OF CHOREA IN A FAMILY

BY

DONALD PATERSON, M.D., F.R.C.P.,

PHYSICIAN TO OUT-PATIENTS, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET; PHYSICIAN FOR DISEASES OF CHILDREN, WESTMINSTER HOSPITAL;

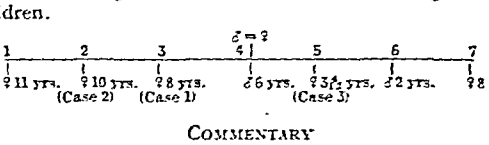
AND

LOUIS J. HORN, M.B., CH.M.SYDNEY,

LATE ASSISTANT CASUALTY MEDICAL OFFICER, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET

The following three cases of chorea, occurring almost simultaneously in sisters of one family, seemed to us to be of sufficient rarity and interest to warrant their being put on record.

Case 1.—E. J., aged 8. There was no previous history of pains or other manifestations of rheumatism. The patient had had tonsillectomy performed at St. Thomas's Hospital at the age of 4. On August 25th, 1930, she came to the out-patient department at Westminster Hospital with well-marked chorea, and was admitted for six weeks. A throat swab showed streptococci. Some septic teeth were extracted while she was in hospital. A second attack of chorea was preceded by a "croupy cough," commencing June 1st, 1931, and she was again admitted. Immediately after discharge she went to a convalescent home, without returning to her own home, and she is still there. No heart lesion was noted.



Case 2.—G. J., aged 10, had suffered on and off previously with pains in the legs. She was first seen in the out-patient department of Westminster Hospital on May 18th, 1929, with a typical attack of chorea. She was admitted as an in-patient for six weeks. Tonsillectomy was performed on June 24th. A throat swab, taken in July, showed a pure culture of *Micrococcus catarrhalis*. On December 4th she came to the out-patient department again with a second attack, milder in this instance. She was put on aspirin, with rest at home, followed by a period in a convalescent home. She gradually improved. On June 15th, 1931, she developed a third moderately severe attack of chorea, preceded some weeks before by a "croupy cough," and was admitted. She is still in hospital, and is improving. She has shown no signs of heart involvement.

Case 3.—G. J., aged 3 years 4 months, was treated at Westminster Hospital in the out-patient department about two years ago for general malnutrition and tonsillitis. There was no complaint of pains or rheumatism. She came again on August 6th, 1931, with a history of slight movements four days previously. They were observed to be typically choreic. The last known attack of sore throat was about two and a half months previously. She was admitted to the wards, and is still an in-patient. Her movements have lessened. There is a soft mitral systolic murmur.

The interesting point of the inquiry is the onset of chorea in the three children of the one family at short intervals, so that they were all suffering from that condition simultaneously. An inspection was made of the home conditions, and revealed that all three patients were accustomed to sleeping in the same room (about 9 by 9 feet in size). The room had one door and one large window, which the mother stated was left partly open at night in favourable weather. The general condition of the house was dirty, but not extremely so. An examination of the other members of the family showed that the father was suffering from what he stated to be "rheumatic arthritis." On examination he looked well, and little joint swelling was seen. His tonsils had been removed in childhood, and his throat was healthy. The mother was healthy in appearance, and had small, clean, atrophic tonsils.

L. J., the eldest child, had no rheumatic history, but had had her tonsils removed (for nephritis). T. J., the fourth child, had no previous rheumatic history, but the mother stated that he had had sore throats and swollen glands in the neck from infancy, and was still suffering from them. On examination, the tonsils were seen to be very large, with pus in the crypts, and his cervical glands were also enlarged. His tonsils are to be removed. D. J., the sixth child, has had no ill-health. The tonsils were noted to be very large, but not obviously septic. The youngest child was a healthy infant.

The following scheme shows the sex and ages of the children.

COMMENTARY

It was pointed out by Longstaff[1] and Atwater[2], in 1905 and 1927 respectively, that the streptococcal diseases, such as erysipelas, septicaemia, scarlet fever, puerperal fever, and rheumatic fever, were inclined to show a synchronicity in incidence and mortality. This argued a certain epidemicity. In the rheumatic wards at the Cheyne Hospital for Children, Chelsea, it was noticed by Sheldon[3] that there were small epidemics of sore throat, followed some two or three weeks later by epidemics of acute rheumatism, and that in those cases which did not actually develop a sore throat a rise of temperature had been noted two to three weeks previously. Sheldon found that the cases in these epidemics were, with one exception, in neighbouring beds.

Alison Glover,[4] in the Milroy Lecture, quoted several instances to show that tonsillitis and subsequent rheumatism assumed epidemic proportions under crowded conditions, and practically disappeared when these conditions

were ameliorated. He took the case of the *Impregnable* Training Establishment in 1912–13 (reported by Dudley). The boys, aged 15½, were housed in three old wooden battleships, the air space was continuous, and the hammocks were 16 inches apart. The incidence of tonsillitis was 397 and of rheumatic fever 43.7 per 1,000 respectively—a very high figure. This dropped to normal proportions on transference of the boys to barracks ashore.

In the report of the health of the Royal Air Force for 1928 a similar epidemic of tonsillitis and acute rheumatism is recorded, although the crowding here was not so marked. The incidence of tonsillitis was 175 and of rheumatism 16.5 per 1,000 respectively.

In the instance under discussion it is suggested, in view of the synchronicity of the attacks and the crowded living conditions, that these three children have either infected one another or have been infected by a possible carrier in the person of the fourth child, the boy with chronically infected tonsils. The latter seems the more likely, since the patient in Case 3 had not seen her sisters for a period of six weeks previous to admission to hospital herself, as the sisters had been in hospital and at a convalescent home for that time. This would imply a very long latent period for chorea.

Conclusions

1. Chorea may assume epidemic proportions in a family where the living conditions show overcrowding.

2. The cases reported support the contention that rheumatism may be contagious in overcrowded conditions.

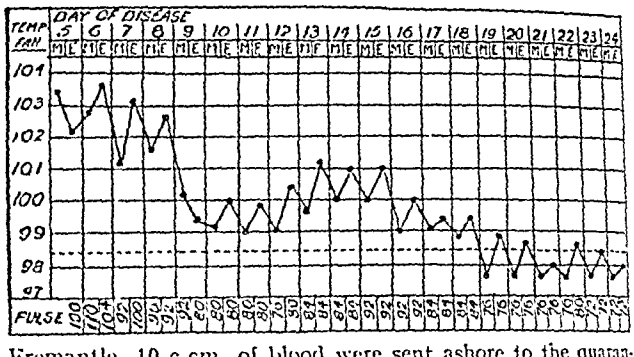
A CASE OF BRILL'S DISEASE

BY

H. M. ROYDS-JONES, M.B. B.S.



The following case seems worth reporting in view of the absence of diagnostic symptoms, and the interesting points arising from it.

History of the Case

A male, aged 49, a vegetable cook working in the galley of a passenger liner with a crew of 400, reported to the ship's surgeon on February 25th, 1931, complaining that he had been feeling dizzy, had pains in the legs, and had been coughing for two days. His temperature was normal and physical examination was negative. He had never lived abroad, but had served in France during the war. At that time there was an epidemic of mild influenza among the crew; his case was diagnosed as influenza and he was given salicylates and alkalis.

On the morning of February 27th his temperature was 103.4° F., and he was moved into the ship's hospital among other influenza patients. He vomited twice that day. On the 28th he complained of nothing but the headache, which had become more intense, and a troublesome cough. That night he was slightly delirious. The temperature began to settle down on March 3rd, and the patient felt much better; but on the 6th it rose again and remained up until the 13th, at which time he felt perfectly well, but weak after being confined to bed. There was no enlargement of the spleen at any time during the illness and no physical signs of disease except a few occasional rales at the bases of the lungs. The bowels, which had been rather free during the first two or three days, were subsequently constipated, and had to be regulated by aperients. A few small pink papules were observed on the back and chest, perhaps a dozen in all; but as these occurred when the ship was in the Indian Ocean, they were put down to the heat and sweating. No spots occurred on the limbs.

In view of the duration of the pyrexia, slight cough, and irregularity of the bowels, the case was diagnosed as probably one of paratyphoid fever, and on March 18th, on arrival at

Fremantle, 10 c.cm. of blood were sent ashore to the quarantine authorities with a request for a Widal test. The result of the test was a negative Widal but a positive Weil-Felix.

Commentary

The following points arise in connexion with this case.

1. It was found impossible to trace the source of infection. This man had not been ashore at any port since sailing from England; and, if we accept a twelve days' incubation period, this would put the date of exposure to infection a day or two prior to the sailing of the ship from London. No lice were ever found in his bunk, in the hospital bed, or on his body; he denies the possibility of any lice while at his home, and of having slept away from home where lice might be present. No rats have ever been seen in the ship since she was launched, and he says that there have never been any in his home. The medical officer of health for Gravesend was communicated with, and he stated that no similar cases had been reported in the borough "for very many years," and he kindly inquired of the port sanitary medical officer, who stated that no cases of typhus or contacts had come into the port.

2. The difficulty of diagnosis was due to the mildness of the symptoms—namely, the total absence of any distinctive rash, no suffusion of the face or conjunctiva, etc.—and to the fact that there had been no cases of Brill's disease or typhus on board. This would have caused the diagnosis of this case to be missed had not a routine Weil-Felix test been carried out. The infection was apparently contracted in England, where the disease in such a mild case, occurring, as this did, during an influenza epidemic, would probably not be diagnosed, and suggests the routine use of the Weil-Felix reaction in prolonged cases of pyrexia with influenzal symptoms in which other causes are not found.

3. All authorities seem agreed that this disease is not communicated direct from case to case. Nicolle,[1] Anderson and Goldberger,[2] and more recently the report of the Typhus Research Commission of the League of the Red Cross Societies to Poland,[3] all agree in indicating the body louse as the means of spread of infection in typhus. In Brill's disease the louse seems to play either no part or a very minor one, and cases do not occur spreading directly through families and communities. This was noted by Brill[4] in America, by Fletcher and Lesslar[5] in the Malay States, and by Hone[6] in South Australia; the latter put forward evidence to show that the spread is in some way connected with the presence of abnormal numbers, or of abnormal activity, of rats or mice. This leads to a point of some importance to shipping companies and port health authorities. At present there is no official recognition by port health and quarantine departments of any difference between typhus and Brill's disease. Typhus is one of the five quarantinable diseases, and if a case occurs on board it leads to

the regulations for quarantinable diseases being enforced and free pratique at ports being withheld Whatever view is held as to whether typhus and Brill's disease are varieties of the same infection or are different diseases presenting similarities, there should be no necessity for including the latter among the quarantinable diseases if the evidence regarding the method of its spread is accepted, as there is no likelihood of a virulent epidemic arising Brill's disease might be made notifiable at ports in a similar way to measles, scarlet fever, venereal disease, etc , when the *Q* and not the *L* flag is flown on entering port

4 There does not seem to be any authoritative statement as to how long after recovery a patient who has once suffered from typhus or Brill's disease will give a positive Weil Felix reaction This point might arise in a case of pyrexia in which the Weil Felix reaction, done as a routine, is found to be positive, and in which the patient has been abroad and may have had a mild attack of Brill's disease that was undiagnosed at the time

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

TREATMENT IN PERNICIOUS ANAEMIA

The striking success which in recent years has been obtained by feeding patients suffering from pernicious anaemia with liver in some of the many available forms, or more recently by some extract of the stomach mucosa, leaves us still in ignorance of the actual cause of the disease Some cases, which at first dramatically improve, after a time relapse, and the increased anaemia and asthenia are not then benefited to the same extent—possibly not at all—by liver or stomach feeding The question, therefore, is, Why is it so?

It appears that in giving liver we are supplying a "something" to the patient which an animal normally has in that wonderful warehouse—its liver If we assume that the liver itself does not manufacture this "something, but rather *stores* it, this possibly explains why we get better results clinically by varying our methods of administering liver and by altering the brand of the preparation of liver extract , because on this assumption we can recognize that the animal's storehouse (liver) may be poorly stocked with the "something"—even in a normal, healthy animal—at the time of killing to procure the extract This something is possibly an amino-acid

Now the gastric mucosa has been found to be of value in replacing liver , this "something" can therefore be probably found in the stomach and stored in the liver In the American medical press it has been recorded that beef muscle, incubated with normal healthy human gastric juice, has been found to be a substitute for liver treatment, whereas feeding with normal gastric juice alone was found ineffective

I venture to record the following case of feeding with beef muscle and gastric juice, which succeeded dramatically for a time, so that this procedure may receive trial by those in charge of refractory cases of pernicious anaemia

Case History

A male patient, aged 61, was sent to me last July by Dr Ainsley Hawes—an advanced case of pernicious anaemia The patient had benefited wonderfully on liver and ventriculin and had received a blood transfusion on eight occasions. Recently, however, he had rapidly relapsed, was extremely weak and ill, with constant vomiting and was taking little interest in his surroundings. His liver and spleen were both enlarged—the spleen could be felt three inches below the costal margin He begged for another transfusion Realizing that it would be of only very temporary benefit alone, I consented on the condition that this temporary improvement should be utilized for an active attempt at treating the disease as well Stating this to the relations, I had no difficulty in getting the patient's daughter-in-law to offer to provide the gastric juice daily

Immediately after the transfusion, which picked him up rapidly, he was given glucose and 15 units of insulin, shortly after, he received 2 oz of pounded beef muscle, which had been incubated for three hours with 2 oz of gastric juice, aspirated two hours after the donor had taken an egg beaten up in milk. This was repeated daily, and also insulin with glucose twice a day The improvement was dramatic , he became active in mind, the vomiting entirely ceased, and the spleen got smaller in two days, at the end of the week being hardly perceptible After ten days he went home to continue the gastric juice beef diet and improved continuously for a month Then he had a bilious attack, disliked the diet, and it was discontinued Since then I hear he is going downhill again rapidly

I have urged, as the donor is perfectly willing to resume, that the treatment should be started again surreptitiously, and that the meat should be varied—mutton, chicken, veal, or rabbit muscle—so that the disguise may be complete

The value of giving glucose and insulin as a general tonic in many grave conditions to tide over a critical period is as yet hardly sufficiently appreciated

Consideration of this case emphasizes the point of view that pernicious anaemia is a deficiency disease, the "something" being contained and made by the action of gastric juice of a healthy person acting on the beef muscle at body heat Obviously beef muscle does not contain it The liver then stores this "something" and supplies it, when necessary, to the blood-forming system

In conclusion, the young lady rapidly learned to pass the tube on herself, and to aspirate her gastric juice perfectly easily with the aid of a mirror; she is quite ready to continue her daily gift for an indefinite period. I hope to add to this preliminary report at a later date.

Leicester ASTLEY V. CLARKE.

HERPES ZOSTER AND ENCEPHALITIS

The following case is, I think, of sufficient interest to be worth publication.

On August 10th, 1931, a married woman complained of severe pain extending from above the left orbit to the top of the head , there was no pain on the right side She also had mild conjunctivitis of the left eye Five days later the typical rash of herpes zoster developed above the left eye and extended through the hair to the top of the head The conjunctiva was now very injected , there was ptosis of the left upper eyelid, and typical ophthalmic zoster

On September 6th she complained of weakness in her left arm, and of inability to grip with the hand, or brush her hair. On examination, the left leg was also found to be weak, but there was no exaggeration of the knee jerk and Kernig's sign was absent There is no keratitis of the left eye so far She eventually developed a left sided hemiplegia

I noticed in the *Epitome* of September 12th (para 197) that André Thomas and J B Buvat had recorded a very similar case They stated that among the numerous nervous manifestations in patients with herpes zoster hemiplegia was one of the most frequent, especially in ophthalmic zoster, but that the relation between the two had not always been firmly established

Reports of Societies

THE WIDENING OPPORTUNITIES OF PHYSICAL TREATMENT

The address from the chair of the new Section of Physical Medicine of the Royal Society of Medicine was delivered on October 16th by Dr. F. G. THOMSON, the first president, who was also the last president of the old Section of Balneology.

Treatment by physical methods, he said, although practised in some forms and to some extent from the earliest times, had never received, until comparatively recently, much serious consideration from the bulk of the medical profession. The main preoccupation of those engaged in practical therapeutics had, with very few exceptions, always been directed to the discovery and administration of pharmacological preparations derived from minerals or plants, and, in later years, in the form of glandular extracts, from animals. For many centuries drug treatment had held the field, to the exclusion of everything else. Instead of becoming fewer and simpler, the remedies appeared to become more numerous and complex. Osler, however, declared that the best physician was he who used the fewest drugs, and although this attitude of mind was rarely pursued to its logical conclusion, there were now many in the profession who would agree with its essential truth. Although certain drugs were of inestimable value in properly selected cases, there were many others whose use and reputation depended more on custom and tradition than on proved utility.

Together with a recognition of the limitations of drug therapy, there had arisen a tendency to place greater reliance on forms of treatment based entirely on physical measures. An outstanding example of this was seen in the great importance that treatment by radium and by *x* rays had assumed in recent years. A department of physiotherapy also was now included in nearly every large general hospital, where increasing numbers of people were treated daily by massage, manipulation, various electrical applications, and light. But although physical treatment was assuming yearly a wider and more important role in practical therapeutics, it still lacked co-ordination of ideas and methods. Until now the subject had been somewhat neglected in the medical curriculum, and, so far as Dr. Thomson was aware, there was no single university or medical school where any serious attempt had been made to introduce the systematic teaching of the different forms of physical medicine.

Physical treatment had been used so long and extensively in the treatment of rheumatic diseases and such metabolic disorders as gout and obesity, that many people might be inclined to associate it almost entirely with those particular diseases. As a matter of fact, it was of much wider application, and there was a great variety of diseases in which at some time or another some form of physical treatment was indicated. No better example could be given of the application of physical treatment in general medicine than the modern way of dealing with pulmonary tuberculosis. Sanatorium treatment, which consisted of rest, unlimited fresh air, suitable diet, and graduated exercises, carefully controlled by the patient's reactions, was physical treatment and nothing else. These same principles, combined with any necessary surgical intervention, proved equally successful in surgical tuberculosis. The change of thought in favour of physical measures was well illustrated in the open-air treatment of medical and surgical tuberculosis. If any physician in the early 'nineties had advised his consumptive patients to discard their chest protectors, overcoats, shawls, and respirators, and to spend their days and nights—more particularly their nights—exposed to the winds of heaven in all sorts of weather, he would have been looked upon as a danger to the community. But the principles underlying sanatorium treatment were now generally recognized as sound; and its results in one of the most insidious, intractable, and dangerous of diseases were satisfactory. It was all the more remarkable that these same principles had not been applied more widely in other chronic infections. One disease which suggested itself was chronic multiple infective arthritis, where the stereotyped forms of treatment by drugs, liniments, baths, radiant heat, and so forth had been, in the majority of cases, perfectly futile. Apart from the removal, if this was possible, of any focus of infection, the only line of treatment which appeared to afford any hope of success was to put the patient in the best possible condition to resist the infection by methods strictly analogous to those employed in chronic tuberculosis.

The numerous diseases for which physical treatment was applicable offered such wide fields for discussion that Dr. Thomson foresaw difficulty in limiting the activities of the Section of Physical Medicine. Although there might be certain technical aspects of the subject of little interest to any but those actively engaged in carrying out physical methods, he felt that the object of the Section should be to consider physical treatment on lines as broad and comprehensive as possible, and to combine, as far as might be, with other Sections by joint meetings to discuss the applicability of such treatment to the cases with which they were particularly concerned. Certain forms of physical treatment were comparatively new, and in some cases more or less experimental in their application. The exponents of any new method were apt to be carried away by enthusiasm, which had to be tempered by further experience. One function which the Section might usefully perform was to make collective investigations into the value of different forms of physical treatment, and to issue reports on these subjects. Many reasons, therefore, pointed to the need for a Section devoted entirely to the study of physical medicine, and, if run on broad and comprehensive lines, he believed that it would prove of very great advantage.

ACUTE OSTEOMYELITIS

At a meeting of the Section of Surgery of the Royal Society of Medicine on November 4th, with Mr. C. H. FAGGE in the chair, a discussion on the treatment of acute osteomyelitis was opened by Mr. GWYNNE WILLIAMS.

The many varieties of acute osteomyelitis, Mr. Williams said, combined with the relative infrequency of the disease, made it difficult for any one person to form a conclusive opinion on its treatment. He defined acute osteomyelitis as a sudden illness associated with fever and with evidence of inflammation of bone, with a history of duration for days rather than weeks. He proposed that the discussion should be limited to acute primary osteomyelitis as found in the long bones, and to forms due to *Staphylococcus aureus*. Results might be considered under four headings: immediate mortality; preservation of the limb; the extent of the resulting necrosis of bone; persistence of suppuration of varying degrees in the bone in after years. During the past twenty years 91 cases had been treated in University College Hospital, of which 7 had occurred in adults and 84 in the growing bones of children. There had been 18 deaths in the series, 10 of them during the first four days after operation; the majority of these must be regarded as due to septicaemia, and were probably incapable of cure by operative treatment. In the remaining group death had occurred in the neighbourhood of the tenth day. These cases had been treated by opening the medulla to the extent to which

pus was visible, and then by plugging or irrigation by the Carrel-Dakin method In most of them, either before or after death, pericarditis or other evidence of widespread infection had developed, and it might be argued that the severity of the surgical procedure was responsible for the dissemination of infection Surgical treatment of acute osteomyelitis had favoured free gutterng of the bone for some years, but recently a more limited attack with the drill and trephine had been attempted Whatever method was used the temperature fell gradually, and it was rare to find a case in which operation produced a crisis Mr Gwynne Williams described a case of osteomyelitis of both tibiae, which had been treated by stripping the periostrum for two thirds of the length of each bone and by drilling a hole in each The result had been a gradual fall of temperature and steady healing of one tibia and sequestrum formation in the other He suggested that if the periosteum was extensively stripped it was neither necessary nor always desirable to open up the bone During post operative treatment the resistance of the patient should be raised if possible, and he considered that these cases did best in the open air He believed in Orr's method of plugging with a vaseline dressing and enclosing the limb in a plaster splint The smell was foul from the wound under this treatment, but the pain was completely relieved If the general condition gave cause for anxiety a plaster bandage could be removed almost as easily as a cotton one In his experience blood transfusion seemed to have little value in cases of infection The preservation of the limb depended on the invasion of neighbouring joints He believed that the less the surgical trauma to the bone the smaller the sequestrum He knew of no evidence on which a considered judgement could be formed on the likelihood of sub equent suppuration in the bone in after years

Mr ERIC LLOYD said that the mortality rate in acute osteomyelitis varied between 20 and 60 per cent, and was commonly in the neighbourhood of 30 to 35 per cent The infection started in the metaphysis of the bone, and Starr had considered that invasion of the medullary cavity occurred late in the disease, he had therefore condemned gutter operations as occasioning unnecessary devitalization of bone, and had pleaded for simple but adequate drainage 'Drain the metaphysis, spare the diaphysis" might almost have been Starr's slogan Spread of infection into the epiphysis or into the joint was rare The commonest direction of spread was probably through the compact bone at its thinnest point where it joined the epiphysis, with subsequent formation of a subperiosteal abscess In patients who recovered after simple incision of the periosteum nature's perforation of the compact bone at the junction with the epiphysis probably provided adequate drainage, but this did not occur often enough to make simple periosteal incision the treatment of election Starr believed that when medullary infection occurred it was by way of the Haversian canals from a subperiosteal abscess, but he held that if drainage was established in the metaphysis the medulla could look after itself Mr Lloyd described two cases in which he had combined Starr s and Orr's methods of treatment with success

Mr W H OGILVIE said that he was a supporter of the older gutter operation He doubted whether the drainage secured by drilling the metaphysis was adequate, and complete healing was hindered in any operation where the walls of an abscess cavity could not fall together Sequestra had subsequently developed in 60 per cent of Starr s patients Orr's method had been valuable during the war, when there was a shortage of dressings and of nursing staff, but it gave rise to much scar tissue and the unnecessary ankylosis of joints Scarring hindered healing if subsequent operations had to be undertaken He considered that the gutter operation should be approached by a flap incision, and the wound closed round Carrel-Dakin tubes, this combined the advantages of the closed and the open wound as regarded scarring and drainage

Mr MAX PAGE was convinced that extensive operations gave rise to sequestra and favoured recurrence Quite half the cases of acute osteomyelitis had bacteraemia, and surgery could do nothing to reduce this He agreed that blood transfusion was disappointing Orr's treatment was impracticable in a closed ward, owing to the foul smell generated, but its success in some cases brought home the thought that pus, provided it was not enclosed, was a useful dressing Packing could be introduced through a trephine hole, and should not be removed in too much of a hurry.

Mr. P C C GARNHAM believed that most sequestra were due, not to osteomyelitis, but to operative interference, and described two cases in which sequestra had formed at the exact site at which the bone had been entered at operation Whenever possible, he thought the bone should be left intact or drained by a small hole made with the minimum of trauma.

Mr C P HOLMAN said that the orthodox treatment of acute osteomyelitis used to be immediate operation, but possibly it might be wiser to leave the patient until the acute stage had begun to subside In ten patients who had been admitted to hospital with subperiosteal abscess he had simply incised the periosteum and packed the wound with gauze coated in bipp, with good results. The majority of cases treated in this way required operation later to remove sequestra He thought it might be advisable to defer operation until the acute stage was past, and he believed that interference with the bone should be reduced to a minimum Orr's treatment could be rendered less offensive by packing the wound with bipp, which would remain sweet for weeks, and by cutting the plaster so that the top dressings could be changed Mr Holman thought that it was better to treat an infected joint by Dr Cotton's method of washing out with 1 in 15,000 mercury perchloride through a needle and cannula than by incision

Mr J P HOSFORD described a case in which spread of infection had occurred through the epiphyseal cartilage into the joint, treatment had been by drainage of the joint, with subsequent complete recovery of function He asked what the treatment of election should be when it was suspected that the epiphyseal cartilage was involved In a small proportion of persons arteries were known to traverse the epiphyseal cartilage, and spread of infection, when it occurred, was probably by way of these abnormal vessels Surgeons hesitated to drill the cartilage, which might itself be uninjured in spite of the extension of infection through it.

Mr O L ADDISON regretted an apparent return to the surgery of 70 years ago, which had been responsible for filling pathological museums with specimens He disagreed that trephining could provide adequate drainage Those who found sequestra following their operations had failed to secure efficient drainage, he had never seen a sequestrum of any size after a thorough gutter operation Osteomyelitis might flare up, even fifty or sixty years after operation, and adequate treatment was always difficult and uncertain He was of the opinion that where there was severe involvement of the femoral shaft amputation was the best treatment Treatment by trephining could never be successful except in the earliest and mildest cases

Mr KENNETH HERITAGE had found the results of Starr's method of treatment satisfactory where the diagnosis was made early. He thought dissemination of infection

following the gutter operation might be due to the use of the gouge; where a trephine was used this danger might be reduced. Immobility—the principle of Orr's treatment—could be secured equally well with a Thomas splint; enclosure in plaster was wrong if the pus had spread under the periosteum, or along the cellular planes of the limb.

In replying, Mr. GWYNNE WILLIAMS said that there was no sure way of telling when the epiphyseal cartilage was involved; the surgeon must wait and watch developments. He did not claim that trephining provided adequate drainage, but he did not believe that this was secured by the gutter operation either. The mortality rate had not been reduced by the gutter operation.

BRITISH ORTHOPAEDIC ASSOCIATION

ANNUAL MEETING

The annual general meeting of the British Orthopaedic Association was held at Newcastle-upon-Tyne on October 30th and 31st. The first morning was devoted to the reading of short papers, and in the afternoon cases were demonstrated at the Royal Victoria Infirmary.

Osteochrondritis Ischio-pubica

Dr. WHATELY DAVIDSON (Newcastle) said that osteochondritis ischio-pubica was a rare condition in which there was limping and pain suggestive of early tuberculosis of the hip, with tenderness and swelling over the ischio-pubic ramus. *X* rays showed a globular swollen appearance of the cartilaginous junction of the rami of the ischium and the pubis. The condition was thought to be traumatic in origin and analogous to osteochrondritis of epiphyses. Symptoms subsided within a few months and the *x*-ray appearances became normal.

End-results of Tuberculosis of the Hip

Mr. JOHN GILMOUR (Newcastle) had followed up a series of eighty-seven cases of tuberculosis of the hip. Conservative treatment in an abduction frame secured recovery of a limited range of movements in a proportion of cases. A short fibrous ankylosis was a satisfactory end-result, but recurring flexion adduction deformity requiring repeated osteotomies was not infrequent. If the hip became unstable and dislocation or wandering acetabulum threatened, an extra-articular arthrodesis was advised.

Mr. NAUGHTON DUNN (Birmingham) said that multiple osteotomies could be avoided if the child whose hip disease had become quiescent was left without apparatus for six months until maximum possible deformity had developed before the osteotomy was performed.

Mr. MCCRAE AITKEN (London) advocated non-weight-bearing unloaded movement after the disease was quiescent. This encouraged recalcification of the femoral head and acetabulum, and prevented flattening of the bearing surfaces.

Mr. T. P. MCMURRAY (Liverpool) strongly recommended conservative treatment, and said that the majority of adequately treated cases returned to work with a strong stable hip.

Calcareous Deposits in the Supraspinatus Tendon

Mr. R. C. ELMSLIE (president) described seven cases of deposition of amorphous calcium in the supraspinatus tendon just above the great tuberosity. This was to be differentiated from fracture of the tuberosity, and from loose bodies in the joint. Very severe pain arose, and excision of the whole sac, including the adjacent part of the tendon, was advised. Symptoms were completely relieved and did not recur.

Mr. R. OLLERENSHAW (Manchester) reported two similar cases. Mr. R. WATSON JONES (Liverpool) said that the condition was exactly analogous to calcification of the semilunar cartilages, intervertebral discs, fibrosed lymph glands, and organizing blood clot, and was due to fibrosis. It occurred in other tendons, notably the tendo Achillis after tenotomy. Occasionally the deposit could be aspirated subcutaneously with complete relief of symptoms.

Treatment of Fracture Shafts of Both Leg Bones

Mr. WATSON JONES (Liverpool) demonstrated a simple portable apparatus by which anatomical reduction of overriding fractures of the shafts of the tibia and fibula could be secured, which allowed immediate fixation in plaster. Reduction was just as perfect as when an open operation was performed, and all the disadvantages of extension methods were avoided. The complete treatment of a case was illustrated by means of a cinematograph film.

Bone Grafts and Fusion Operations for the Spine

Mr. S. A. S. MALKIN (Nottingham) compared the relative merits of Albee's, Hey Groves's, Gibson's, and Hibb's operations for fusing the spinous processes and laminae in tuberculosis of the spine. He was in favour of laying a double tibial graft on the laminae, one on either side of the bases of the spinous processes. Solid bony fusion could be demonstrated radiologically.

INJURIES OF MUSCLES AND TENDONS

Mr. H. C. EDWARDS (London) introduced a discussion on injuries of muscles and tendons, and based his opening remarks on the paper for which he was awarded the Robert Jones medal and prize for 1931. He said that muscle strains should be treated by early exercise to avoid adhesions and prevent wasting of the muscle as a whole. Massage was entirely useless. As a general rule ruptured muscles should be sutured in order to allow early exercise and movement. Late operations by fascial implantations where the retracted muscle belly had fully shortened was of no value. Pathological rupture of the long head of the biceps in chronic arthritis of the shoulder, "drummer's rupture" of the extensor longus pollicis, and spontaneous rupture of this tendon following fractures of the lower end of the radius, were discussed. Other occupational muscle injuries were rupture of the tendo Achillis in mountaineers, of the pectoralis major in boxers, of the external oblique in reapers, and the adductor longus in cavalrymen. Abdominal pain, tenderness, and rigidity in rupture of the rectus abdominis was to be distinguished from acute appendicitis. Avulsion of the extensor tendon of the finger (mallet finger) was best treated by operation. Open wounds of the flexor tendons gave very poor results. Immediate operation in the hospital casualty department was strongly deprecated, not only because the operation was *too* difficult for any but a very experienced operator, but because the risk of infection was much less after several days' interval. Bunnell's buried suture, and immediate active movements with no immobilization, were essential.

Mr. ROCYN JONES (London) had personally sustained a partial rupture of the calf muscles and had found raising the heel of the shoe to be of no value. Local strapping was beneficial.

Mr. H. PLATT (Manchester) said that the only reliable sign of complete rupture of the tendo Achillis was an abnormal range of dorsiflection at the ankle-joint. Operative treatment was then necessary. Mallet finger should be treated conservatively by fixation for six weeks. Although the terminal joint required hyperextension, both of the other joints should be flexed.

Mr. W. TRETHOWAN (London) had observed the results of treatment by massage and exercises of a complete

rupture of the tendo Achillis in a professional dancer who had refused operation. The tendon united with half an inch of lengthening, and although the patient did subsequently dance, she was now much less efficient, and had recently returned asking for operative treatment.

Mr. WATSON JONES (Liverpool) said that myositis ossificans at the elbow- and knee-joints was purely traumatic, and due to avulsion of a muscle insertion with periosteum. It was not an inevitable complication, and was curable by suturing the periosteum back to the bone. In cut finger tendons, the suture of the profundus tendon alone was advised. This tendon provided ample power, and, if the sublimis tendon was completely cut away, adhesion formation was minimized.

Mr. ELMSLIE said that he had never seen a really satisfactory result when a flexor tendon of the finger had been cut below the distal palmar crease. Almost every speaker who had taken part in the discussion was in agreement, and had spoken in very strong terms of the danger of allowing casualty officers to suture cut tendons. The operation was never to be regarded as an emergency. Not only should several days elapse before it was undertaken, but the patient should be admitted to the wards, treated as a major case, and only operated upon by senior surgeons, preferably those accustomed to tendon surgery.

BACTERIOPHAGE AND THE CHOLERA PROBLEM

At a meeting of the Edinburgh Branch of the Royal Society of Tropical Medicine and Hygiene, on October 22nd, in the Clinical Laboratory of the Royal Infirmary, Edinburgh, with Lieut.-Colonel E. D. W. GREIG, I.M.S., president of the Branch, in the chair, Lieut.-Colonel J. MORISON, I.M.S., read a paper on the bacteriophage in relation to cholera and dysentery.

After describing the features of bacteriophage action, and referring to the different views as to the nature of the agent, the lecturer commended, as a working hypothesis, d'Herelle's contention that it was an independent living organism. So long ago as 1923 Bail had noticed that a race of dysentery phage could be divided into types, at least two of which, when obtained pure, each evoked a resistance to its own action in a bacterium grown in its presence. The bacterium was no longer lysable by this type of phage, but could still be lysed by the other. This observation had been confirmed, and additional types had been described by others, but Asheshov first grasped the idea that the various types supplemented each other, and that *in vivo*, as *in vitro*, the action of a multitype bacteriophage might be very different from that of a single-type bacteriophage. A distinction should be drawn between a polyvalent bacteriophage which lysed serologically different bacteria, and a multitype bacteriophage, composed of types of one race, each of which lysed the bacteria made resistant to other types of that race. Asheshov, working in Patna, had described three types of cholera bacteriophage, which he called A, B, and C, and devised for their identification a simple and ingenious technique by which a quantitative analysis of a cholera bacteriophage could be made. Two quantitative analysis procedures had been devised, one by Asheshov and his assistant, Dr. Saranjan Khan, the other by the speaker. These had concordant results, but each had its drawbacks. Colonel Morison's assistant, Dr. A. C. Vardon, had now combined the two methods into one, which was simple and rapid. The result of such examinations had been to show that in nature one or more types were frequently absent. The dysentery bacteriophage had been studied at Shillong on similar lines. Two types were isolated by picking off plaques, and repeated subculturing; these types were called G and H. Finally, seven in all were obtained. Of these seven, six had been found in India, and one in a phage obtained from d'Herelle's laboratory in Paris; the last had also three of the Indian types. When a bacteriophage had n types present, the method of analysis required that a strain of dysentery (Shiga or Flexner, etc.) be made resistant to the types, taken $n-1$ at a time. It was increasingly difficult to prepare strains of dysentery resistant to five and six types of phage, since these multiple-resistant strains grew feebly, but quadruple-resistant strains were very useful in determining phages G, H, J, K, and L. In obtaining these multiple-resistant cultures of dysentery and cholera it was found that certain types and combinations of types made a smooth culture rough, and that other combinations apparently transformed a rough culture into a smooth. Rough strains of cholera obtained from patients at the end of an epidemic were all A-resistant, but these when made resistant also to B or to C phages became smooth. Similarly an originally smooth Flexner became rough when made resistant to H, J, and K phages, but was still smooth when made resistant to G, H, and K. The Shillong therapeutic phage was a mixture of cholera and polyvalent dysentery phages, prepared from many natural phages, and grown on a number of strains of vibrios and dysentery bacilli. These methods secured the presence of as many "types" as possible, and, before issue, each batch was analysed in the way described. The use of a mixed phage had been suggested by the finding of a strong dysentery and a strong cholera phage in a patient recovering from cholera, and was justified for village use, since early cases of cholera were frequently mistaken for dysentery, and some acute dysenteric infections were indistinguishable from cholera.

In Assam, where cholera was endemic, the melting of the Himalayan snow and the first rise of certain silted rivers over their fouled mud flats determined, if cholera was present, the hot-weather epidemics; the sudden fall of the rivers, with rapid drainage of the villages on their banks, seemed to precede the autumn epidemics. This held for Assam and for that part of Bengal north and east of the Ganges. The absence of cholera in Assam during the wettest months of the year (July and August) was probably due to the isolation of every village, which rain and mud so effectively secured in those parts. The monthly figures for cholera in official reports gave no true picture of the spread of cholera. In villages it was rarely difficult to find the actual person who brought the cholera, and to obtain evidence of how it was distributed. During a study of a village epidemic, and of its treatment by bacteriophage, an indication was obtained of how village epidemics might possibly be cut short, and the spread of the disease be hindered. In one epidemic the infection was brought by a party returning from an infected village two days' journey distant. The funeral feast held on the day the first victim died resulted directly and indirectly in 143 cases of cholera in a population of 700. The disease during the first nine days caused fifty-eight deaths among eighty cases. Among the patients who became ill on the ninth day seven out of nine died. There was no evidence that the virulence of the disease was abating. That evening bacteriophage was distributed to all who would take or were allowed to take it, and its distribution was continued till the end of the epidemic. Of those becoming ill after the arrival of the bacteriophage, six did not receive bacteriophage and all died, while of fifty-seven who received the bacteriophage only six died. To test the question what would happen could the bacteriophage be given to the

first cases, two notorious centres for cholera had been under observation. In the one, Naogaon with a population of nearly 500,000, bacteriophage was distributed to every village along the banks of the Kalang River. In the other, Habigunj, through which flowed an equally dangerous stream, the usual methods of vaccination and treatment with essential oils were carried out. During the first six months of 1930 sixty-three scattered cases of suspected cholera were treated by the headmen of the villages in Naogaon, but no outbreak ensued, and there had been no outbreak so far during 1931. In the Habigunj area there were two severe epidemics during 1930, and a small one in the spring of 1931. On the occurrence of this third epidemic the Public Health Department had ordered the adoption of bacteriophage treatment in Habigunj, and if this was effectively carried out the experiment would enter on a new phase. Naogaon had not experienced such freedom from cholera during the previous ten years, but the results of 1932 were awaited, since that would be the fifth year from the last epidemic, and there was a susceptible population unprotected either by a recent epidemic or by vaccination. To the proper disposal of excreta, which had banished cholera from Europe, to the disinfection of infected water supplies which had protected cities like Baghdad and Poona, and to vaccination, which could never be given a fair trial since the vaccinators always arrived after the disease had started, was now added a method which attacked the disease at its beginning by bringing about the development of an agent active against the vibrio itself in the first cases of an epidemic—cases which might themselves disseminate the bacteriophage as they ordinarily disseminated the cholera vibrio.

INTRACRANIAL TUMOURS

A meeting of the Liverpool Medical Institution on October 29th, with the president, Professor W. Blair Bell, in the chair, took the form of a symposium on intracranial tumours.

Dr. T. B. Davie discussed the pathology of these tumours, and classified them as: (1) gliomas, 41.2 per cent.; (2) meningiomas, 12.5 per cent.; (3) auditory nerve tumours, 9.4 per cent.; (4) pituitary and hypophyseal stalk tumours, 21.7 per cent.; (5) secondary carcinomas, 4.7 per cent.; (6) granulomas, 2.75 per cent.; (7) blood-vessel tumours, 1.7 per cent.; and (8) miscellaneous tumours. The metastatic tumours, granulomas, and rarer tumours of the miscellaneous group were omitted from further consideration. The pathology of the different tumour groups was illustrated by mounted specimens, stained sections, and lantern slides. Several examples of acoustic nerve tumours were shown, and their essentially fibromatous structure was demonstrated. This structure was contrasted with the endotheliomatous structure of the meningiomas. Included among the meningiomas was one occurring in the cerebello-pontine angle, and another which had become malignant. The gliomas were dealt with more fully, the classification adopted being that of Bailey and Cushing, with some of the modifications suggested by Carmichael and by Penfield. A simplified routine of fixing and staining the gliomata was recommended, and examples of most of the commoner glial tumours were given. In conclusion, the age incidence and site of occurrence of the commoner gliomata were discussed. The value of knowledge of the aspect of intracranial tumours—as a guide to the nature and scope of surgical intervention, and as a basis for the formulation of a rational prognosis—was made the plea for further and more general study of these interesting growths.

Dr. Henry Cohen, dealing with the mechanism of symptom production in cerebral tumour, pointed out that the symptomatology arose firstly from the presence of a foreign body, gradually increasing in size, in a relatively non-expansile chamber—the skull; and secondly, from the site and nature of the foreign body. Hence the complete diagnosis must comprise an answer to all three aspects of this problem—Whether? Where? What? The general signs of cerebral tumour resulted from a gradually increasing intracranial pressure. This depended on, and varied with, the size and rate of growth of the tumour, and interference with the circulation of blood and cerebro-spinal fluid, especially the latter. The localizing signs of a tumour were produced by increase, perversion, and decrease or abolition of the cerebral function; these resulted from the destruction of nerve elements, pressure on, with displacement of, nerve elements, and resulting loss of function, and interference with the circulation of blood and cerebro-spinal fluid, especially the former. A detailed description of these general signs followed, with points in the differential diagnosis from other conditions giving rise to the classical triad of headache, vomiting, and papilloedema. Special emphasis was laid on generalized epileptiform convulsions as an early expression of increased intracranial pressure. The relative infrequency of papilloedema in early supratentorial lesions was stressed. False localizing signs in cerebral tumour were considered in some detail, and the necessity was emphasized of careful inspection, palpation, percussion, and auscultation of the cranium. Accessory means of diagnosis were mainly examinations of the cerebro-spinal fluid and radiography; other methods—such as brain puncture (Pfeiffer), and the electrical resistance method of Bohnenkamp and Schwäh—were of interest, but not of routine clinical value. The use of manometry, combined ventricular and lumbar puncture, and especially the value of cerebro-spinal fluid examinations in excluding other conditions which might simulate tumour, was commended, though the danger of lumbar puncture, particularly in subtentorial neoplasms, was very real. Radiography was of help, both directly and indirectly, after the injection of contrast media. A brief description was given of the methods of encephalography and ventriculography after air injection, and several lantern slides showing examples of radiological changes in cerebral tumour were presented. In attempting the pre-operative diagnosis of the nature of the tumour, the factors requiring most careful consideration were: the age of the patient, the site of the tumour, the mode of evolution of symptoms, evidences of disease elsewhere, and such accessory tests as serological, cutaneous, blood and cerebro-spinal fluid examinations, auscultation, and radiography.

Professor R. E. Kelly considered the surgical aspects. He said that trephining was probably one of the oldest surgical operations, going as far back as neolithic times; Hippocrates, Galen, and Celsus had used the trephine and had given practical hints for employing it. In a work by Scultetus in 1650 there were numerous illustrations of head operations performed by instruments similar to those in use at the present time. Broca might be looked upon as the founder of cranial surgery, for he was the first to trephine for abscess. Professor Kelly then demonstrated the more modern instruments of Hudson, de Martell, and Souttar, and discussed the particular areas in which he had found these instruments useful. He then showed a cinematograph film of a cranial operation—a tuberculoma. The tumour was quite easily shelled out; the patient, a boy, had made a complete recovery. Professor Kelly also exhibited four other patients, from three of whom meningiomas had been removed.

Reviews

TISSUE CULTURE

Tissue Culture in Relation to Experimental Biology,[1] by E C Cragin, reviews the contributions of tissue culture to many different fields of biological and medical inquiry In the introduction the author defends the wide scope of his book by maintaining that a consideration of these various branches of biological science in relation to tissue culture is a useful way of obtaining a general view of the wide range of cell activities After dealing with the origin and history of tissue culture he passes to the technique, which he sets out in commendable detail The routine procedure described is for many laboratories perhaps unduly complicated, but when the work has to be done in a hot and dusty city, or in an unsuitable building, the numerous precautions recommended might be valuable A comprehensive summary of the mass of literature relating to the appearance and mode of growth in culture of different types of tissue is followed by an account of the conditions of growth *in vitro* This section includes an interesting and illuminating discussion of the vexed question of dedifferentiation of tissue during cultivation The cytology of cells *in vitro* (structure, reproduction, migration, etc) and their physiology (metabolism, muscular contractility, etc) are then described, and a short section is devoted to the work on the cultivation *in vitro* of plant tissues, which has so far proved the least fruitful application of the technique The rest of the book relates to the many applications of tissue culture to medical subjects—pharmacology, radiology, pathology, bacteriology, and immunology—and it ends with a chapter on tissue culture and cancer

This is a useful and interesting survey of the immense tissue culture literature in a readably brief form, and the author is to be congratulated on the excellent arrangement of his matter More criticism and discussion of the works quoted might have been included with advantage, especially in the last chapter (on cancer), where some of the results referred to as established facts are by no means universally accepted as such One of the minor faults of the book is the large number of errors in the spelling of authors' names the reviewer encountered one Polish name which was spelt in four different ways An extensive and very useful bibliography is appended, but as many of the papers included are not mentioned in the text, it would have been more valuable had it been divided into smaller sections according to the subject matter of the papers, each section following its appropriate chapter

On finishing Dr Cragin's book the reader can hardly fail to be impressed by the enormous possibilities of tissue culture as a research method, and, indeed, there is hardly any branch of medicine or biology which the technique cannot be made to serve in some degree In the introduction the author states that tissue culture can easily be done in any laboratory This is perfectly true There is however, a deceptive simplicity about the method which has been responsible for much unsound research A beginner equipped with a general medical or scientific education can learn the essential principles of tissue culture in a month, but, unless he is working in close contact with those who are already expert in the technique only long experience will enable him to interpret the material correctly, to distinguish between normality and degeneration, and to diagnose and overcome technical difficulties Moreover, it is one thing to be proficient in the tissue culture method, and quite another to apply it successfully to a specific problem, and the most competent tissue culturist will produce results of little value unless he is either a specialist himself in some particular branch of science (pathology, biochemistry, embryology, etc), or is able to collaborate with such a specialist

THE CARDIAC CYCLE

Dr Harrington Sainsbury insists upon the recognition of physical principles in the consideration of physiological problems In his monograph on *The Cardiac Cycle*[2] many common sense arguments are marshalled in support of an unorthodox conception of the production of the arterial pulse Briefly, he holds that the pulse-wave is generated by the impact of blood upon the closed aortic valves during the isometric phase of ventricular contraction, and that the wave is "sent coursing through the aorta and its branchings down to the arterioles" The stretching of the arterial wall is regarded as the expression of "momentum" carried by the pulse wave Since momentum is defined physically as the product of mass and rate of movement of the mass, it is difficult to see how a vibration without any expulsion of blood into the arterial tree can add any momentum to that already possessed by the moving stream of blood before the impact strikes on the closed aortic valves It would seem more reasonable to agree with Wiggers that the oscillations in the column of blood produced during the isometric phase of ventricular contraction are insignificant, and are represented by small preliminary undulations on the carotid pulse curve before the abrupt large wave resulting from the onset of the ejection phase

Whatever criticism is levelled at Dr Harrington Sainsbury's work, it must be recognized that his opinions are the outcome of a very full consideration of detail and first principles His stimulating section on the bulbus aortae is well thought out as a whole, but is not convincing in the matter of the action of the aortic valves In explaining that these are opened up only centrally during the ejection phase of ventricular systole, the author puts forward the view that any greater movement of the valves would be impossible, because it would entail the movement of the blood *en masse* Surely the elasticity of the bulbus aortae would allow of more than minimal opening of the aortic valves? The pathological arguments brought to sustain his view are more impressive

This volume concludes with a description of the mechanics of the circulation of the lymph The importance of the pulse wave in promoting lymph flow is stressed, and a logical discussion of other factors is provided Dr Sainsbury has obviously given great care and thought to the difficult problems which he seeks to solve While his views are open to criticism, there can be no doubt of the sincerity, enthusiasm, and lucidity with which his arguments are set forth

THE PSYCHOLOGY OF EARLY CHILDHOOD

The great importance of the study of the pre school period of a child's life is now recognized A good deal of attention has recently been directed to it The establishment of nursery schools, and the extension of child welfare work to children between 2 and 5 years of age, has been urged upon local authorities by the Board of Education and the Ministry of Health Yet it remains

true, as has been several times pointed out, that during this range of age in which habit formation is so active, and where wise guidance is of such great value for future welfare, there is a greater lack of expert assistance than at any other period of childhood. A new edition of the work of William Stern of Hamburg, on *The Psychology of Early Childhood up to the Sixth Year of Age*,[1] is opportune and welcome. This is the second edition of the English translation of this work, and it has been enlarged and completely revised in accordance with the sixth German edition.

It need scarcely be said that the book is full and authoritative; indeed, since its first publication in 1924 it has been recognized as containing a large amount of original and pioneer work, and as being a standard volume which could not be ignored by anyone interested or working in the field of study to which it has reference. To some its general method and outlook may begin to appear old-fashioned, but the revision it has undergone for this new edition fully recognizes the most important advances which have been made in the field of child psychology, and submits them to discussion and criticism. A number of the chapters in the sections dealing with enjoyment and creative activity, and with effort, emotion, and will, have been entirely rewritten. Much fuller treatment has been given to the experimental examination of young children by specific tests. Some trenchant, but wise, criticisms of psycho-analysis in general, and especially of Freudian psycho-analysis in young children, are now included; the pedagogic theories and practices of the Montessori school are submitted to examination with not altogether favourable results; and in general the theory of personality, and the personal standpoint, on which previous editions have been based, has been maintained, and is emphasized perhaps even more than before.

At the end of the book are two supplements—one by Professor Kurt Lewin of Berlin, who deals with the expressive movements of children by means of film photographs, and one by Professor Heinz Werner of Hamburg, on the subject of magic attitudes in early childhood. It will be seen that the work is very thorough, in German fashion. Scarcely any detail is overlooked, though it is curious that the very real light which the modern study of mental defectiveness can throw upon the normal psychology of children is, to all intents and purposes, ignored. In places, perhaps, this attention to detail is a little overpowering, and detracts from the interest which a broader and more general method of analysis might have induced. One general statement should, however, be quoted, not only as being very important in itself, but also as indicating one of the standpoints from which the subject has been dealt with:

"Our task is not to apply the 'normal measure' of our own psychic powers and nature to the child and to make a note of the points where he falls short of the standard, but rather to understand the different nature of the child as being typically characteristic of his positive divergent individuality."

PERIMETRY

A third edition of *The Principles and Practice of Perimetry*,[2] by Luther C. Peter, professor of ophthalmology of the University of Pennsylvania, has now appeared. The volume is introduced by a short summary of the anatomy and physiology of the visual paths and the physiological principles of vision. In the first of these subjects a considerable amount of matter has been added, particularly with reference to the recent work of Brouwer and Zeeman and Putnam on the visual paths. The treatment of the physiology of vision is necessarily brief in a work of this kind; this, however, cannot reasonably be taken as an excuse for lapses into unintelligibility. It is difficult, for example, to follow the definition suggested for visual acuity (p. 40): "By this term is meant either the ability of the eye to recognize minute points of definite size, as separate points at a definite distance, spacial perception, or to recognize a point of definite size at a definite distance."

The section on physiology is followed by a description of the general principles of mapping out the visual field by the perimeter or the campimeter, which is followed by a good account of the many modifications of the standard instruments which have been devised for the purpose, the value of some of the newer and more expensive of these being carefully and justly appraised. This is followed by a general discussion of the pathological changes which may be found in the visual fields—the various types of scotomata, changes in the colour fields, and so on. A new and prominent feature of the present edition is the introduction of the "anatomic or physiologic method" of reading the visual fields. According to this method the chart represents the patient's field as viewed by the examiner in a position facing the patient, instead of depicting the field (according to custom) as looked at by the patient himself. The former method has the theoretical advantage of conforming to the general usage in projection in most other branches of ophthalmology and general medicine, but it makes some of the charts considerably different from those to which we have become accustomed. The remainder of the book deals with the many pathological and functional conditions which produce abnormal changes in the visual fields. These are discussed in considerable detail, and the many personal observations of the author are amply supplemented by references to the voluminous literature which has accumulated round the subject. The volume forms a useful source of information on many of the more difficult problems of ocular and cerebral diagnosis.

ANTI-MOSQUITO MEASURES

The literature dealing with the application of various anti-mosquito measures has become so extensive that the average worker has great difficulty in keeping in touch with the different methods advocated. Major Gordon Covell, in his work entitled *Malaria Control by Anti-Mosquito Measures*,[5] has placed in the hands of medical men a short, concise, and extremely practical account of the various methods used to control malaria. The important measures of housing, screening, oiling, and the use of Paris green are discussed in detail, and reference is made to all the methods advocated in the literature. This most useful book will be of the very greatest value to field-workers in all countries. A feature of it is the comprehensive bibliography, which contains 570 references to books and articles, arranged under the headings of the various measures dealt with. This collection of the literature will be welcomed by all malariologists, and the appendix, giving a list of the sources and prices of the various apparatus used in carrying out anti-mosquito measures, is invaluable.

NOTES ON BOOKS

HOWELL'S *Text Book of Physiology*[1] is now so well known and so widely appreciated in this country, and the appearance of new editions so regular an annual event, that the latest edition needs but little comment. It is enough to say that the standard which has earned for it a world-wide reputation has been well maintained, and that the work has been brought well up to date. The reviewer is of the opinion that there is no more useful presentation of the point of view of present-day American physiology.

The many friends of *Mrs. Dose the Doctor's Wife* will be glad to hear that Miss JOYCE DENNYS has written and illustrated a sequel to that lively piece of satire, in time for the Christmas gift-book season. *Repeated Doses*[2] ("The mixture to be taken as before") is very good fun. Where the author and artist gets her knowledge of Harley Street and general practice from we do not know; but it is plain that she has first-hand acquaintance with both sides of the medical life, and if her digs at doctors are a little unkind she shows herself once again a witty and understanding admirer of the doctor's wife.

The appearance of vol. xi of MELLOR'S *Chemistry*[3] brings the author's work a notable stage nearer completion. Our reviews of the first ten volumes have already described the work as one of extraordinary magnitude, including a wonderful wealth of detail arranged on a plan which we believe must render it the most comprehensive as well as the most convenient work of reference of its kind that has yet been published. Vol. xi deals with tellurium, chromium, molybdenum, and tungsten. It continues the characteristics established in the former volumes, and maintains the same high standard of excellence. Dr. Mellor has a genius for connecting facts and events into attractive narrative. We observe that each separate volume has its own index; it seems to us, however, that a general index to all the volumes will also be highly desirable. If the whole work is to be fully cross-indexed, the index will itself be a very substantial volume.

In *The Great Physician: A Short Life of Sir William Osler*[4] there is presented, to those who were not fortunate enough to know him and might be deterred by the length of Professor Harvey Cushing's famous *Life* of his master, a beautifully printed and illustrated account of "the physician of two continents." The author, EDITH GITTINGS REID of Baltimore, had the privilege of Sir William's acquaintance, of access to many of his letters, and help from a number of his devoted friends. She also acknowledges her great indebtedness to Professor Cushing's biography, of which to a considerable extent her book is almost necessarily an abstract. She writes in a style which will probably appeal more to those accustomed to the American press than it will to British readers. There are some minor inaccuracies about medical matters; but these should not worry the lay reader, and he may not notice the different spellings (Egerton and Edgerton Y. Davis) of Osler's *nom de plume*.

Mr. H. L. BAYNHAM, publisher, of 49, Queen Victoria Street, London, E.C.4, has prepared a new edition for 1931 of the *London Register of Nursing Homes and Medical Institutions*. Some particulars are given of accommodation for paying patients in London voluntary hospitals.

[1] *Text-Book of Physiology*. By William H. Howell, Ph.D., M.D., Sc.D., LL.D. Eleventh edition, thoroughly revised. Philadelphia and London: W. B. Saunders Company. 1930. (Pp. 1,099; 305 figures. 30s. net.)

[2] *Repeated Doses*. Written and illustrated by Joyce Dennys. London: J. Lane, The Bodley Head, Ltd. 1931. (Pp. 157; illustrated. 5s. net.)

[3] *A Comprehensive Treatise on Inorganic and Theoretical Chemistry*. By J. W. Mellor, D.Sc., F.R.S. Vol. xi. London and New York: Longmans, Green and Co. 1931. (Pp. xii + 909; 51 figures. 63s. net.)

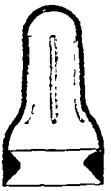
PREPARATIONS AND APPLIANCES



AN IMPROVED TEAT FOR INFANTS' FEEDING-BOTTLES

Dr. A. D. MACDONALD (Department of Pharmacology, University of Manchester) writes:

The rubber teats commonly used on infants' feeding-bottles are made by the repeated immersion of a suitably shaped mould in a rubber solution, and the teat, when a suitable thickness is obtained, is "cold-vulcanized"—a process which involves the exposure of the article to the action of sulphur monochloride, either as a vapour or in solution. Such treatment produces a certain hardness and resilience. The whole process is slow, and the glass moulds require frequent replacement. It is also unsatisfactory, in that it is not particularly healthy for the workers; indeed, the manufacturer who uses it is required to obey rather stringent Home Office regulations. The cold-vulcanized rubber teat is not an altogether satisfactory makeshift; in France its sale is forbidden by law, but certain loopholes have it possible for the regulations to be evaded on technical grounds.

The laboratory staff of Messrs. Macinlop, Ltd., Manchester, have been experimenting during the past year on the production of a moulded heat-vulcanized teat which would be free from the more serious objections which characterize the standard cold-vulcanized patterns. I have acted in an advisory capacity during the development of the moulded teat, and subjected the teat to a series of laboratory tests. It is clearly important to ascertain that the processes of manufacture do not introduce into the rubber any harmful substance.

For the production of a heat-vulcanized article the rubber is first mixed with a carefully controlled proportion of sulphur and subsidiary ingredients. The heat treatment is usually accomplished by inserting a weighed quantity of the mixed or "compounded" rubber in a steel mould, which is placed under hydraulic pressure between the platens of a steam-heated press. The degree of vulcanization is determined in part by the composition of the mixed rubber, and also by the temperature and duration of the heat treatment. In contrast to cold vulcanization, which is largely a surface treatment, heat vulcanization progresses uniformly throughout the mass, so that all portions of the finished article have the same characteristics. In addition to careful selection of the compound and all raw materials used, manufacturing operations must be carried out with strict attention to cleanliness, and the finished moulded teats are finally sterilized before wrapping.

In all my observations the new teats have been compared with those marketed by a well-known firm, and known to be manufactured by the older process. When new and unboiled the moulded teat is not quite as translucent as the cold-vulcanized article. It feels a little firmer and more substantial, and is free from any stickiness, which cannot always be claimed for the other. In rough tests of toughness and elasticity there is little to choose between them.

Most important of the advantages that can be claimed for the moulded teat is that it can be sterilized repeatedly by boiling in water. I have boiled one for four days of about eight hours, without apparent deterioration. The cold-vulcanized teat, after thirty minutes' boiling, generally loses resilience, and becomes cracked and rough. These cracks, if the teats are used thereafter, might well be irritant, and make strict cleanliness difficult.

Milk is not affected in reaction, as tested by indicators, nor in palatability, when the new teat is immersed in it. Indeed, I have pumped a small quantity of milk through a teat repeatedly throughout an hour, and the appearance, reaction, and flavour of the milk are unaffected. When a teat has been immersed in milk for twenty-four hours the flavour of the milk is impaired, becoming "rubbery"; but this is an academic objection, and applies equally to the cold-vulcanized product.

I have applied rubber strips, cut from the teats, to the skin of the forearm and axilla, retaining them in place by strips of zinc-oxide plaster. No reaction whatever was provoked in the skin by the heat-vulcanized rubber; indeed, the zinc-oxide plaster produced a slight erythema, from which the rubber had shielded the area it covered.

Through the kindness of Dr. Catherine Chisholm, the moulded teats were then given a thorough clinical trial. On her recommendation they were lengthened, so that they could reach and stimulate the palate and dorsum of the tongue, if required, and thus produce more powerful suction. The shoulders were further strengthened, and the retaining ring improved, so that there is no risk of the infant sucking or pulling the teat from the bottle. For bottles with openings at either end a suitable valve of similar material has been moulded. It is believed that these teats will shortly be available for general use.

British Medical Journal

SATURDAY, NOVEMBER 14th, 1931

THE GROWING AND MOVING BOY

Towards the end of the war Lord Dawson of Penn brought forward his proposal for the formation of a network of "health centres" throughout the country. These health centres, while affording facilities for the best kind of team work, were also to play an important part in recognizing the physical conditions that lead to disease. The orthopaedic centres now established are, in a way, a specialized fulfilment of the main idea, and already the class of case they are receiving and treating is in a far less advanced stage than when Alton first opened its wards. Practitioners not only now diagnose surgical tuberculous conditions earlier, but press upon parents the necessity for early institutional treatment. Now another lead in the same direction has been given by Lord Dawson. In his address at the opening of the new sanatorium at Epsom College (reported in our issue of October 10th, p. 666) he called upon school medical officers to "study boys when they are in movement." This is a new conception of medical examination of great importance. It is both bold and original, for it is a call to recognize tendencies and susceptibilities even before these become the early signs of disease. Let us see where such a practice would lead, and what changes in methods of examination, keeping of records, and work for the school medical officer it would entail.

The customary general medical examination of to-day puts on record age, height, weight, chest measurement, and chest expansion. Then, as a rule, there are records concerning the various systems. But measurements pass from recollection or interest as soon as noted on paper, for they are so many cold facts that convey to the mind only a faint idea of the physical make-up of the individual. In the examination of the systems the records rarely note anything but abnormalities, and make no effort to assess the "degree of wellness" or efficiency of the system under inspection. In the Royal Air Force it was recognized that the examiner must try to estimate degrees of wellness and concern himself little, or not at all, with illness. Special tests were devised—such as the breath-holding test, fatigue test, exercise tolerance test, and balancing test—with a view to estimating and obtaining some record of the efficiency of various systems. These proved invaluable. During the late war they were applied to youths fresh from school, pilots who had broken down in training, or been wounded, or flown for long hours; and those in charge of the examinations grew to recognize types at sight without special examination or reference to their record. Thus, the stigmata of cardiovascular debility, nervous instability, and of other types of disordered function, made themselves patent to the eye and mind of medical officers trained to assess varying degrees of health rather than of illness. The individuals of each type reacted alike under the stress of training and war, although weight, height, chest measurements, and similar data showed extreme variations within the type; moreover, they responded successfully to pre-selection for the kind of flying they were best suited to carry out, and a large number of the new entry were, by suitably chosen methods of physical training, made to advance from an unsuitable type to one able to respond well to stress and strain. This is real "health centre medicine" of the best.

So to-day the special examiners of the Royal Air Force, while continuing exact and detailed records, are able in a very large proportion of cases to classify their material accurately by eye, by observing the body in movement. Any medical officer to a school who attended the assessing of the Royal Air Force pilots and candidates could acquire in a short time the skill to classify boys coming under his observation into a number of types. He could check his observations by occasional full examinations, including suitable tests, and by observing the achievement of the boys in their school games and their response to treatment when ill. The usual records are cold, and give no living picture of the individual; but here is a method that cannot fail to interest the school medical officer, because it will, once his eye is trained, instantly conjure up almost a composite portrait of the individual. Moreover, classification of the living and moving boy in this way can be taught by the doctor to masters, thus building a bridge of mutual interest and collaboration between the two. It is to be hoped that medical officers to public schools will respond to this new and inspiring call, and produce work as valuable for growing boys as that of the original Special Board of the Royal Flying Corps in the emergency of the war. It should not be difficult, in conference, to agree upon a few preliminary broad types, and so begin at once to make the road Lord Dawson has indicated.

Lord Dawson, in his address, referred also to the education of the skin. This is of great importance, and further knowledge would certainly show us how to diminish some of the dread of the Lent Term now present in the minds of parents and masters alike. The Turk considers the Englishman mad when he takes a bath. "To get into a bowl of water, wash the dirt off and then roll in it" seems to him the height of insanity. Are not school baths, in which boy follows boy in rapid succession, an almost perfect method of conveying infection of the skin and mucous membrane from one individual to another? No one supposes that the mere emptying of a bath leaves it surgically clean. Showers would certainly be more efficacious and hygienic, would be cheap, and use less water than an ordinary bath. In many places in Sweden all who enter the swimming baths have to wash themselves with soap under a hot shower before being allowed to swim; these shower rooms are used instead of baths, and the healthiness of

the Swede is too well known to emphasize. Experiments to prove a point such as this would be easy to carry out in one house of a boarding school, and they would come well within the duties of school medical officers who take a broad view of their appointment. Lord Dawson has indeed opened for them new interests and new functions that will eventually bear fruit for the nation if they respond to his call.

ECONOMY IN INDIAN HEALTH SERVICES

The special session of the Indian Legislative Assembly, the business of which is confined to the Government's Emergency Finance Bill, met at Delhi on November 4th and will presumably complete its business by the 21st, the date for which the Council of State has been summoned. The Bill is designed to meet a deficit of some 39 crores (that is, about 390 million rupees) during the next eighteen months, and those upon whom its burden will fall with most weight have at least the consolation that its operation is, according to the Finance Member, Sir George Schuster, expected to produce a surplus which will justify relief during the financial year 1933–34. The Bill imposes sweeping retrenchments in Government services generally, and especially in military expenditure, an emergency cut in all salaries at a flat rate of 10 per cent., and drastic increase of all taxation except the customs duty on exports.

The salary cuts, which are expected to effect a saving of 128 lakhs, will come into force as from December 1st, and apply equally to civil and army officers. In the case of officers whose rights are guaranteed under the Government of India Act—a class which includes the Indian Medical Service—the necessary legislation will be introduced in the Imperial Parliament at the first opportunity. The main lines of the scheme were announced at the close of the autumn session in Delhi, and interest therefore centres at the moment rather on the recommendations of the committees to which was entrusted the task of formulating detailed proposals for retrenchment and the decisions on these recommendations now announced for the first time. Some of these have a special claim upon our attention, not only as affecting the service conditions of members of the Indian Medical Service, but also as constituting a grave menace to the long overdue development of the basic health services. They fall into two groups: those primarily affecting service conditions, and those primarily affecting services. Under the first head, in addition to the basic salary cuts, the General Purposes Subcommittee proposed the withdrawal of the Lee concessions and the abolition of the exemption from income tax of pensions, leave and deputation salaries, and allowances payable outside India. On these proposals we can frame no better comment than that supplied by the Finance Member in announcing their rejection in his opening speech last week, as reported by the *Times* correspondent in Delhi. He pointed out that the concessions were granted to meet grievances and inequalities as between different classes of officer, held, after most searching inquiry, to be fully established. To withdraw them would be to restore the inequalities, and would entail palpable injustice and class discrimination. For the rest, the Government of India has no legal means of recovering Indian income tax on payments due outside India; the pensions rights of existing pensioners, and of those who have already entered a pensionable service, cannot be altered; and the proposal to superimpose taxation on leave pay upon salary cuts already pushed to an extreme limit is not one which the Government should, or could, entertain.

The recommendations for retrenchment in existing or projected services include the abolition of the appointments of Director-General I.M.S., and Public Health Commissioner with the Government of India, and of the separate establishment of the Director-General, which includes six medical officers, one of whom acts as an assistant to the Public Health Commissioner. It is recommended that the responsible heads of the existing central departments should be replaced by two isolated officers, a Medical Adviser to the Government of India and a Public Health Adviser to the Government of India, each to be "of sufficient standing and experience to function as a Deputy Secretary, and to draw about a Deputy Secretary's pay." The existing nucleus of a central health and medical department would be absorbed in the Army Department on the one hand, and the civil Department of Health, Education, and Lands on the other. The subcommittee's justification of these recommendations is hardly convincing. Holding that the D.G.I.M.S. and his office are merely a survival of the pre-reform period, it opines that medical service questions do not require a civil head of the Medical Services any more than is the case with any other All-India Service operating largely in the major Provinces; that co-ordination of the medical policies of the major Provinces may *per se* be a desirable object, but the existing constitution does not demand it; and that neither do the Provinces ask for it, nor can India in her present financial condition afford to undertake it. On the military side the subcommittee considers it only right that all such matters should be transferred to the Army Department, but does not find it necessary to discuss the efficiency value for the Service of a head with adequate status, including access to the Viceroy, and reasonable departmental resources. As regards the Public Health Commissioner, it bases its recommendations, with cheerful inconsequence, upon those of the Inchcape Economy Committee of 1923, ignoring alike the cogency of the reasons which led to their rejection in the earlier period of financial stringency, and the practice and experience of all civilized Governments, federal as well as unitary, in the matter of central health departments, and the grave implications of the Indian morbidity and mortality returns at the

present time. Both these recommendations have been rejected by the Government of India. The report as yet available do not inform us of the grounds for this decision, but we may hazard a guess that it is based on three general considerations: appreciation of the actual health obligations, national and international, of the Central Government, under the existing constitution; realization of the essential part played by a strong central department of health in the sound development of any federal State; and, perhaps not less, recognition of the importance for the efficiency of military and civil services alike, especially during a period of transition and doubt such as the present, of a responsible head with adequate status.

On two more recommendations of the subcommittee the decision of the Government is not mentioned in the reports so far received. These are the suspension of the annual grant of 5½ lakhs to the Central Research Fund, and the reduction of the estimate for the first year's work of the new School of Tropical Hygiene at Calcutta. We hope and believe that the former of these entails only a further postponement of the creation of a Central Research Institute, already the subject of inquiry by two special scientific commissions and much overdue, and not a curtailment of the existing minimum programme of basic research. While it is only proper that all possible economy should be observed in the administration of the Calcutta School of Hygiene, the recommendations of the subcommittee are to be regretted, not merely because they suggest a somewhat cavalier attitude towards the commitments undertaken by the Government of India in accepting the munificent gift of the Rockefeller Trustees, but because of the implied assumption either that India can obtain in the open market the services of first-class scientists at anything less than competitive rates, or that India can afford to dispense with such services. To those who hold this view or find in public health and research services the most appropriate field for retrenchment—and reports from Delhi suggest that in India, at least, their number is not negligible—we would recommend a study of the statement by Colonel W. G. King, Sir Ronald Ross, and the late Sir W. J. Simpson (quoted in our leading article of April 14th, 1923) on public health and medical research in India, which pointed out that the mean expectation of life of the Indian male at birth, which was 24.59 in 1891, had diminished by 1911 to 22.59, while in England it had risen from 40.17 in 1841 to 51.50 in 1910–12. They should also study the latest reports of the Public Health Commissioner, whose office and functions they find superfluous. From these they will learn that the Indian death rate for 1928 was nearly double that of England and Wales, and thrice that of New Zealand, while the infant death rate, a sensitive index of the value of public health effort, was nearly two and a half times that of England and Wales, and about five times that of New Zealand for the same year. The Report of the Simon Commission will inform them that the annual deaths from preventable disease are estimated at five or six millions. In face of such facts the vital question for India would seem to be whether curtailment of public health and research services is not a method of economy too extravagant to be seriously considered.

EPHEDRINE AND PSEUDO-EPHEDRINE

Ephedrine was introduced as a cure for asthma about seven years ago and has rapidly attained a great popularity. The original source was the Chinese plant *Ephedra vulgaris*, and the disturbed condition of China in recent years has resulted in the supply being scarcely adequate to meet the demand. Lieut.-Colonel Chopra and his co-workers have just published[1] the results of a careful study of the Indian ephedras, which was made in order to see if any of these could serve as a source of the alkaloid. They analysed the alkaloidal content of a number of species grown in different localities, and also studied the seasonal variation. They found that two species (*E. gerardiana* and *E. nebrodensis*) contained from 0.5 to 2 per cent. of ephedrine. These yields equal or even surpass those obtained from Chinese plants. *E. intermedia* gave a good yield of total alkaloids, most of which consisted of pseudo-ephedrine. The alkaloidal content in all species showed great seasonal variation, which depended on the rainfall and therefore was different in different localities. The alkaloid yield during the wet months was only one-third of that obtained from plants collected during the dry months. These researches have therefore resulted in establishing a new source of ephedrine, and the authors mention that the Indian export of ephedra leaves is now at least 25 per cent. of the Chinese export. They have also studied the relative therapeutic values of ephedrine and pseudo-ephedrine. They found that ephedrine, when given regularly for asthma, produced a variety of disagreeable side-effects. Palpitation, tachycardia, fainting fits, constipation, and digestive disturbances were among the effects noted. A still more important fact was that patients with cardiac disease tended to become decompensated when given ephedrine regularly in large doses. The authors found that ephedrine produced a more powerful vasoconstrictor action than did pseudo-ephedrine, but that the former depressed, whilst the latter stimulated, the myocardium. On the other hand, the two drugs produced an equal action on the respiratory tract. Clinical tests showed that ephedrine and pseudo-ephedrine were equally effective in relieving asthma, but that the latter caused fewer unpleasant side-actions. "If the use of this alkaloid (pseudo-ephedrine) is extended in the treatment of asthma and other conditions in which ephedrine is being used, not only will the cost of treatment be reduced, but it may be possible to avoid the unpleasant side-effects of the latter group." The results obtained by Lieut.-Colonel Chopra and his co-workers are interesting and important, first from an economic point of view, and secondly, because they suggest an advance in the treatment of asthma. It is to be hoped that clinicians in this country will study the relative merits of ephedrine and pseudo-ephedrine.

THE RED CROSS TRANSFUSION SERVICE

It is announced that the Medical Research Council and the British Red Cross Society have appointed Dr H F Brewer, senior demonstrator of pathology at St Bartholomew's Hospital, to be medical officer to the Blood Transfusion Service organized by the Red Cross His duties will be to supervise the examination of volunteers for transfusion, collate information on the effect of transfusion on donors, and to carry out researches into blood grouping, so that the transfusion service may be kept abreast of the latest developments in surgery and haematology. St Bartholomew's Hospital is providing the laboratory facilities Some account of the work of this service was given by Mr Geoffrey L Keynes at the meeting of the Medical Society of London on October 26th, and briefly reported in the *British Medical Journal* of October 31st (p 801) The service has now a ten years' history, and the number of calls upon it has grown steadily each year, with the exception of a short period when the liver treatment of pernicious anaemia first came to be widely adopted, and obviated the necessity in many cases for successive blood transfusions Last year only 52 transfusions for pernicious anaemia were given, though there were 140 transfusions for anaemias of other forms In 1929 the number of transfusions carried out was 1,333, in 1930 the number rose to 1,627, and by the end of this year it is expected that 2,000 calls will have been made upon this service The membership of the service is now over 1,100, of whom about one fifth are women Very many social organizations are represented on the list of volunteers No payment is made, but all expenses are refunded, including time lost from work, but in most cases the donor, if required in the daytime, is able to return to his work within an hour More than a hundred hospitals have called for the service A very careful record is kept of the nature of the calls and the result of the transfusion In more than half the transfusions the result is described as "good," "very good," or "excellent," and only in 10 per cent is "no improvement" recorded During 1930 the number of distinct conditions for which transfusion was given was 148, and the medical and surgical cases were almost equal in numbers Transfusion was given also in 217 obstetrical or gynaecological cases As many as 449 transfusions were given in cases of disease affecting the alimentary canal (carcinoma 106, colitis 52, duodenal and gastric ulcer 291) Blood transfusion was given last year in 33 cases of fracture and severe injury, in 22 cases of osteomyelitis, in 37 of septicaemia and pyaemia, and in 42 of uterine fibroids Though the operation is not painful or harmful to the donor, those responsible for the service are a little in doubt as to the effect of frequent bestowals Mr Keynes, at the meeting of the Medical Society of London, stated that a certain donor in France had given his blood 450 times, and that at present in London there was a man who was anxious to emulate his example, but those concerned hesitated to allow him to do so It appears that blood grouping is imperfectly understood by some who ask for transfusion for their patients, for they persist in requesting the services of the universal donors, with the result that these are over-used, and donors in the other groups are not used at all.

LEPTOSPIROSIS IN THE ANDAMANS

In an Indian Medical Research Memoir (No 20, March, 1931)[1] Lieut-Colonel J Taylor and Dr A N Goyle describe the result of their investigation of a severe type of jaundice which occurs in the penal settlement around Port Blair in South Andaman Island Previous work, notably that of Barber in 1926, had shown the leptospiral nature of this disease, but no thorough clinical and laboratory investigation of the condition had been undertaken prior to the work recorded in this memoir After a brief historical survey of jaundice in the Andamans, and a description of the infected area and its population, the authors give the results of their clinical and laboratory investigation of sixty four cases of this disease Clinically, the condition differed little from Weil's disease as it occurs in other parts of the world The incubation period was from six to eight days, the onset acute, with fever, prostration, pains in the body, muscular tenderness, injection of the conjunctivae, and frequently albuminuria Jaundice was absent in 31 per cent of the cases, when present it made its appearance, as a rule, on the fourth or fifth day of disease Secondary fever was noted in 19 per cent of cases, and the mortality was 18 7 per cent, about midway between that obtaining in the Japanese mines outbreak investigated by Inada and his colleagues in 1916, and the low rate of 4 5 per cent observed in the British and French armies on the Western front during the great war Illustrative cases of different degrees of severity are described in detail, and the differential diagnosis is discussed The laboratory investigation brought out certain points of considerable interest It has long been recognized that direct examination of human material, with the possible exception of urine, is of little use as a diagnostic procedure, and Taylor and Goyle are of like opinion In the past reliance was placed on guinea pig inoculation, either with blood collected early in the disease or with urine in the later stages, as a means to diagnosis, but in this investigation only one guinea pig out of twenty two inoculated with blood became infected, and no better success was obtained when urine was the inoculum On the other hand, blood cultures made in Noguchi's semi-solid leptospiral medium, or Fletcher's modification of it, were usually positive when blood was collected during the first four or five days of disease Later in the disease there are the various serological tests available for diagnosis, such as agglutination, complement-fixation, the adhesion test, and Pfeiffer's reaction But here one must not forget that the pathogenic leptospira fall into a number of serological groups which bear little or no relation either to the type of disease or to its geographical distribution so that unless one were in possession of a variety of strains, including the local strains, serological reactions might be of little value In fact, Taylor and Goyle's findings emphasize this point, for twenty four out of the twenty-eight Andaman strains of lepto-pira examined serologically formed a group reacting with none of the serums prepared from a representative collection of human, rat, and dog strains As elsewhere, Weil's disease in the Andamans was found to be associated

[1] *Leptospirosis in the Andamans* By Lieut-Colonel J Taylor, D S O, M D D P H I M S and Amar Nath Goyle, M B, Ph D Indian Medical Research Memoir, No 20 Calcutta Thacker, Spink and Co 1931 (8, or Rs 6)

with wet conditions. The seasonal prevalence was that of the south-west monsoon, and cases were practically confined to adult males whose work entailed prolonged contact with stagnant water. Work in the paddy fields was responsible for a considerable number of cases, and the authors recommend the application of calcium cyanamide fertilizer to infected fields as a prophylactic measure likely to be effective. The memoir contains an appendix giving a useful summary of our present knowledge of leptospiral infections.

DRUG POTS

With the advance of pharmacy as a science, and the gradual disappearance of the bottle of medicine in favour of tablets, the furniture of the chemists' shops is changing rapidly. The huge carboys, with cabalistic signs on the glass, and the coloured liquid inside, which used to shine so gloriously on a foggy day in London, have gone as completely as the ordered rows of drug pots and the stoppered bottles on the shelves behind the counter. Mr. Geoffrey Eliot Howard, therefore, has done well to describe some of them before it is too late, and the Medici Society to reproduce their shape and colour in a series of excellent plates.[1] Mr. Howard classifies these drug pots rather too rigidly into decennial periods, each identifiable by the character of its ornamentation. He has also enlisted the services of Mr. C. J. S. Thompson to explain the nature and uses of the various drugs which the jars contained. This table is the more easily understood if it be remembered that U and V are interchangeable. The table might have been amplified with advantage by describing the cryptic alchemical signs which often ornament both drug pots and bottles. Added to the general description are short articles on posset pots, the pill slab, the barber's bowl, wine cups, and wine pots, all of which have long since gone out of use and become "museum pieces." There are one or two small slips which may be rectified in any future edition. It was Dr. William Bullein, not Andrew Boorde, who described the apothecary as the "physician's cook," and the barber's dish (p. 76) could only have been used as a receptacle for blood in cases of emergency. The physician always recommended the quantity of blood to be taken away in a stated number of ounces, unless it was "ad deliquium," and the metal bleeding-bowl was therefore marked on its inner surface with lines representing ounces, and had a flattened portion in its circle, where it could be held against the arm.

MEDICAL HYDROLOGY

The annual meeting of the International Society of Medical Hydrology was held in Amsterdam from October 30th to November 3rd. In the absence of the president (Professor W. Thayer), Dr. J. Van Breeman presided. The honorary secretaries were Dr. E. P. Poulton (London) and Dr. W. S. C. Copeman (London). An inaugural banquet was given to the 120 or so members who attended the meeting by the Dutch Society for the Study of Rheumatism. This was followed by a concert. On the next day the society was officially welcomed in the morning by high officials of the Dutch Government and representatives of the public health services. It was pointed out that rheumatic problems were now definitely considered in Holland to justify inclusion under the heading of "public health," and that this lead was now being followed in other countries, which were awaking to the grave social significance of the rheumatic diseases. In the afternoon a discussion on "The factor of chill in disease" was opened at the university by Professor Loghem, who gave an account of an epidemiological experiment which he had inaugurated with the aid of 7,000 colleagues throughout the country over a period of thirty-seven weeks. He was able to show that the mortality curve from pneumonia and other bronchial affections (excluding the mortality due to senility) ran parallel with the ground temperature curve over this period. Other speakers included Dr. Schade (Germany), Dr. R. Fortescue Fox (London), Professor Wybauw (Belgium), Professor Prusík (Czechoslovakia), and Dr. Baudoin (France). At a council meeting the retiring chairman, Dr. Fortescue Fox, inducted his successor, Dr. E. P. Poulton, into the chair, and Dr. R. Keller (Switzerland) was elected honorary secretary jointly with Dr. W. S. C. Copeman. On the Sunday a tour of the city of Amsterdam was provided by the hosts, followed by a discussion at the Institute of Hygiene, opened by Dr. A. Häberlin (Germany), on the treatment of non-tuberculous children by the seaside—a subject discussed by him at the Annual Meeting of the British Medical Association at Eastbourne last July.[1] The members visited the clinics of Professors Snapper (internal medicine) and Brouwer (neurology), where recent research work was shown and discussed. A clinical meeting was held on the last morning at the Institute for Physical Therapy, of which the acting president (Dr. Van Breeman) has been director for twenty-six years, proving himself thereby to have been amongst the pioneers in this form of treatment in Europe. The Ligue International Contre le Rhumatisme afterwards held its annual meeting, at which Dr. Fortescue Fox was re-elected chairman, and Dr. Van Breeman secretary.

VITAMIN A CONTENT OF BUTTER AND MARGARINE

Miss Barbara Morgan and Dr. Katharine Coward recently published[2] estimations of the vitamin A content of a sample of fresh summer butter and of a "vitamin margarine." Their tests showed that the butter and margarine had an approximately equal vitamin A content, and that the potency of each was about one-thirtieth that of a standard cod-liver oil. The authors point out that these results confirm the claim of the makers of the margarine that their product has a vitamin A content equal to that of butter. Miss Morgan and Dr. Coward's findings are of interest in connexion with the investigation into the activity of vitamin concentrates, of which an account appeared recently in these columns.[3] It will be recalled that four preparations were tested for their content of various vitamins. The vitamin A content was tested in two cases, the vitamin C content in three cases, and the vitamin D content in one case. Reviewing these investigations, we said:

[1] *Early English Drug Jars.* By Geoffrey Eliot Howard. London: The Medici Society, Ltd. (10s. 6d.)

[1] *British Medical Journal*, August 22nd, 1931, p. 331.
[2] *Lancet*, 1931, ii, 758.
[3] *British Medical Journal*, July 11th, 1931, p. 71.

"The results can be considered fairly satisfactory as regards vitamin A, for both products tested had an activity similar to that of cod liver oil," and, further, "The three tests for vitamin C were very disappointing, for two were completely negative" The purpose of the tests undertaken on our behalf was to estimate how much reliance the medical practitioner could place on the vitamin concentrates prepared by firms of repute. In discussing the significance of the results obtained we remarked "It is evident from the results obtained that the problem of preparing on a commercial scale stable concentrates of vitamin A and C has not yet been fully solved, at any rate in the case of preparations put up in the form of foods" Since the results of the tests were so much more favourable in respect of vitamin A than of vitamin C, it was perhaps a little unfair to bracket vitamin A concentrates with vitamin C concentrates in a single generalization We are the more glad, therefore, to note that the results obtained by *Miss Morgan and Dr. Coward in the case of vitamin A* concentrates added to margarine appear to be completely satisfactory, not only in respect of the presence of this vitamin, but also of its stability It is a very difficult problem to mix such delicate active principles as those contained in vitamin concentrates with other substances to make palatable foods and yet to avoid rendering them unstable, and we have no wish to underrate the successes already achieved in this matter by manufacturers of the highest standing.

BRITISH EMPIRE CANCER CAMPAIGN

*In the absence of Lord Reading, Sir Charles Gordon-*Watson presided at the quarterly meeting of the Grand Council of the British Empire Cancer Campaign, held on November 10th On the recommendations of the Executive Council and the Scientific Advisory Committee a further grant for one year of £600 was made to the Cancer Research Committee of the Marie Curie Hospital, also of £300 to Mrs E K Dawson of Edinburgh, and of £50 to Mr. E Nevill Willmer of Cambridge Sir Charles Gordon-Watson, as chairman of the Investigation Committee, reported in detail the whole of the investigations which had been made by the Campaign in connexion with the diagnostic claims of Dr Bendien of Zeist, Holland After reading the contents of the letter which had been sent by the Investigation Committee to the scientific press,[1] expressing the opinion that the method of diagnosis could not be as yet accepted as reliable, Sir Charles pointed out emphatically that in his official correspondence Dr. Bendien had never made claims concerning the treatment of cancer, nor had a shred of evidence been submitted to the Campaign in support of his ability to treat cancer patients successfully A vote of grateful thanks was accorded by the Grand Council to Sir William Morris, Bt, for his generous gift to the Campaign of £25,000 for the specific purpose of the establishment of a radiological research fellowship at Mount Vernon Hospital All arrangements in connexion with the establishment of this William Morris Research Fellowship were delegated to a joint committee, consisting of representatives of the Mount Vernon Hospital and members of the Scientific Advisory Committee of the Campaign

[1] *British Medical Journal*, October 10th, p 677

The work to be carried out under the Fellowship will be both clinical and laboratory, and it is hoped that it will be possible fairly soon to install the necessary equipment at Mount Vernon Hospital The trustees in charge of the funds are Sir Richard Garton, Mr J. Beaumont Pease, and Mr. F. C. Goodenough, members of the Finance Committee of the Campaign

PATHOLOGICAL SPECIMENS BY POST

The Postmaster General requests us to remind members of the medical profession of the regulations governing the postal transmission of pathological specimens sent for medical examination or analysis He informs us that pathological specimens improperly packed have been observed in the post, and draws attention to the serious risk of infection to officers of the post office and of contamination to the mails in the event of leakage of such packets The regulations are as follows:

Deleterious liquids or substances, though otherwise prohibited from transmission by post may be sent for medical examination or analysis to a recognized medical laboratory or institute, whether or not belonging to a public health authority, or to a qualified medical practitioner or veterinary surgeon within the United Kingdom, by *Letter Post and on no account by Parcel Post*, under the following conditions An such liquid or substance must be enclosed in a receptacle hermetically sealed or otherwise securely closed, which receptacle must itself be placed in a strong wooden leather or metal case in such a way that it cannot shift about and with a sufficient quantity of some absorbent material (such as sawdust or cotton wool) so packed about the receptacle as absolutely to prevent any possible leakage from the package in the event of damage to the receptacle The packet so made up must be conspicuously marked 'Fragile with care' and bear the words Pathological specimen Any packet of the kind found in the parcel post or found in the letter post not packed and marked as directed, will be at once stopped and destroyed with all its wrappings and enclosures Further any person who sends by post a deleterious liquid or substance for medical examination or analysis otherwise than as provided by these regulations is liable to prosecution If receptacles are supplied by a laboratory or institute they should be submitted to the secretary, General Post Office, in order to ascertain whether they are regarded as complying with the regulations

Sir E Hilton Young, who succeeds Mr Neville Chamberlain as Minister of Health, was the first (and has so far been the only) layman to serve on the General Medical Council since its formation in 1858 He was appointed by the King on the advice of the Privy Council on May 23rd, 1926, to fill the vacancy on the Council caused by the resignation of Sir Francis Champneys.

The Thomas Vicary Lecture will be delivered at the Royal College of Surgeons of England by Colonel W. P. MacArthur, D S O, M D, on Thursday December 10th, at 5 o'clock. His subject is "The surgeon and old-time plague."

We regret to announce the death at Bournemouth, on November 5th, of Mr Bilton Pollard, consulting surgeon to University College Hospital, and to the Queen's Hospital for Children, London We hope to publish a memoir, with portrait, in our next issue.

THE RELATIVE VALUE OF RADIOTHERAPY IN THE TREATMENT OF CANCERS OF THE UPPER AIR PASSAGES

SEMON LECTURE BY MR. DOUGLAS HARMER

The annual Semon Lecture, under the auspices of the University of London, was delivered by Mr. W. Douglas Harmer, F.R.C.S., at the house of the Royal Society of Medicine on November 5th. Mr. Harmer devoted the lecture to a review of the relative value of radiotherapy in the treatment of cancers of the upper air passages.

The lecturer began by remarking that until recently few centres with adequate facilities for radiotherapy existed, but the position had gradually improved. The British Empire Cancer Campaign, the National Radium Commission, and the Medical Research Council had now nineteen centres, in addition to those hospitals which had been given radium by the King Edward's Hospital Fund. It was to be hoped that before long every hospital would realize that it was impossible to administer radiation treatment properly unless all patients suitable for it were handed over to a group of specialists—surgeon, pathologist, physicist, radiologist—between whom there must be close co-operation. At St. Bartholomew's Hospital researches had been proceeding since 1913, and recently he had been connected with another unit—the combined Radium Institute and Mount Vernon Hospital, which was now one of the most important centres in the country and comparable with the great foundations abroad.

After emphasizing the importance of early diagnosis, and pointing out that practitioners must be trained to send their patients, on the first suspicion of malignancy, to such centres as those mentioned, Mr. Harmer discussed the choice of treatment—a very difficult problem. Experience of all the various methods would decide between surgery, diathermy, radiation, or a combination of them, according to the nature and extent of the disease. If a comparison must be made between surgery and radiation, all the cases should be placed in one of three groups: the operable, borderline, and inoperable. On making an analysis of all patients examined at radium centres and non-radium centres, it would be found that in operable cases the results were about the same at both kinds of centres; in advanced cases the results at the radium centres would be found superior, because of the greater variety of treatment offered, and if all the cases in the three groups were taken together, the radium centres would score heavily.

Effects of Radiation

Nearly all cancers in the upper air passages, Mr. Harmer continued, were radio-sensitive to some extent, but, owing to their depth from the surface, it was difficult to deliver an adequate tissue dose. Radium, applied on the surface or interstitially, in contradistinction to *x* rays, must be considered as a "short-range gun." Clinically and experimentally, it had been noted that the best results were obtained with radium when it was applied in close apposition to the lesion. In illustration of this, he pointed out that whereas in cancers strictly localized to the vocal cords a large percentage of good results was secured, and recurrences only took place at the anterior commissure or below the cord, in advanced cases with subglottic extensions the results had been bad, the chief reason being failure to cover the growth with the radium. It was important to irradiate uniformly the whole of the diseased area; this could be done more certainly with needles than with seeds; if possible, the needles should be distributed around the tumour, rather than inserted within it. The use of small doses over long periods had certainly given better results than large doses applied for a short time. With regard to filtration, he believed that physicists were to blame for advising the use of filters so thin as 0.5 mm. platinum. Except in very experienced hands, it was safer to employ thicker filters, even up to 1 mm. With such filtration radium caused very little damage to the surrounding tissues, and needles could safely be placed close to, or into, bones without fear of necrosis.

In considering the effects of radiation, it should be borne in mind that syphilities, chronic alcoholics, and persons seriously debilitated or anaemic, rarely responded well. Of equal importance were the radiation sensitivity of different grades of cancers and the condition of the stroma. Although there was no experimental evidence of a stimulating effect of radiation on the growth of tumours, this might occur clinically if too small a dose were given. No doubt, previous treatment often made cancer radio-resistant to further applications, but the time elapsing, and the nature and extent of the recurrence, must be considered before deciding on a repetition of the treatment. Above all, steps should be taken, before such repetition, to verify the diagnosis, so that a delayed radium burn might not be mistakenly irradiated as a recurrence of the cancer. No patient who had received radiation treatment at some other centre should be given *x* rays or radium until all the details of the previous treatment had been obtained.

Post-irradiation changes might be classified as follows: (1) total disappearance of growth, the tissues regaining a normal appearance; (2) fibrosis or partial healing; (3) oedema, possibly due to a specific type of infection, and always of serious significance; (4) radiation sores, to be distinguished from the painless and rapidly healing normal reactions; (5) necrosis, a complication occurring more particularly in the larynx, but rare if adequate filtration had been employed, and care taken to prevent sepsis; and (6) pain, as distinct from that ensuing upon radium burns, and appearing as severe neuralgia, due to chronic sepsis, ulceration, or fibrosis, or signifying that the whole disease had not been destroyed.

Cancers of the Larynx

Mr. Harmer then discussed separately the different regions in respect to the occurrence of cancer. Intrinsic carcinoma of the larynx, he said, could be diagnosed early while it was an entirely local disease, and, given an intelligent selection of cases, the results obtained by surgery had been very good indeed. The poor results often following surgery in operable cases were due chiefly to the fact that very few patients could be safely treated by laryngo-fissure; yet the majority of laryngologists still preferred surgery to radiation, because in most hands the latter gave such unsatisfactory results, and the dangers were considerable owing to faulty treatment. The general experience was that carcinoma of the ventricular band was highly radio-sensitive, while that of the cord was favourable for radiation, and that of the subglottic region resistant. There was no agreement at present as to the best method of irradiating, but the lecturer considered that buried radium had given such good results in his own cases as to make that the method of choice. If on first treating these operable cases with radium the disease did not disappear at once, it would usually be arrested, and the line of further treatment could be decided upon deliberately. As a rule, radiation should not be repeated unless the patient was unfitted for laryngectomy; small recurrences could sometimes be treated with radium a second time, but surgery should be carefully considered.

The larynx offered one of the best examples of the short-range efficacy of the gamma rays. To insert the radium a modification of Ledoux's operation (fenestration) was suitable for growths absolutely localized to one vocal

cord or band. When the growth had crossed the middle line the needles must be placed bilaterally; when it had extended down into the subglottic region the principle of Hautant's operation, or some modification thereof, should be employed, and long needles inserted. To prevent complications, sepsis must be avoided at all costs by gentleness in the manipulation of the tissue, by complete and careful haemostasis, and by closing the skin wound completely. To prevent oedema, perichondritis, and late reactions, full filtration was necessary (up to 0·8 mm platinum). Tracheotomy should not be performed if the opposite cord was movable and the glottis adequate. With these precautions he had treated eight cases of this operable group, seven of the patients were living and free from disease, two of them after six years and one after five.

In borderline cases radiation combined with surgery was capable of giving good results. Personally he preferred the use of radium interstitially after removal of the thyroid and cricoid cartilages, with pre- and post-operative radiation. When a growth had extended beyond the limits of the laryngeal cartilages or through them, so that the tissues of the neck were invaded, and particularly when there were glands on both sides of the neck, laryngectomy should not be undertaken.

Altogether, although the results of radium treatment in most centres had proved unsatisfactory, the lecturer believed this to be due to faulty technique, inadequate dosage, and an under-estimation of the extent of the disease. In his own unit the percentage of cures in the operable cases appeared to be at least as good as with operation. The time had arrived when the question should be asked whether it was ever safe to perform a laryngectomy unless the patient had received preliminary radiation treatment in some form. Then, if the disease was not cleared up by radiation within three months, or if any induration remained in the larynx, it was safer to advise laryngectomy than to repeat radium treatment, unless very intense radiation had been employed, laryngectomy could safely be performed. Even in inoperable cases some relief of symptoms and prolongation of life could be obtained by radium. If the growth had infiltrated the cartilages extensively, or had perforated into the neck, radium should not be employed interstitially, better results could be obtained with less risk of sepsis by external irradiation with *x* rays or radium, followed by intubation with radium.

In a brief note on cancers of the hypopharynx, in which he included those of the pyriform fossa, of the posterior pharyngeal wall, and extrinsic laryngeal growths, the lecturer said that he considered a combination of surgery and radiation to be a better treatment than simple excision.

Nasal Growths

Extrinsic growths starting in the skin of the nose were either rodent ulcer or squamous celled carcinoma. In all types of rodent ulcer radiation was better than excision, but in resistant growths excision by diathermy was indicated, and was preferable to the knife. Surface irradiation by beta and gamma rays gave good results in early lesions, but needling was preferable for advanced cases and recurrences. Carcinoma might commence spontaneously, or develop in scar tissue or in a previously existing rodent ulcer, lupus, or even endothelioma. It had a chronic course, penetrating deeply and extending widely; although persisting for years, it rarely affected the lymphatic glands or produced metastases. Such nasal carcinomas behaved quite unlike carcinoma in any other part of the body. The best method of treatment was to use radium on a mould, giving split doses for two to four weeks, and supplementing occasionally by buried radium along the edge of the lesion. These cancers showed an inveterate tendency to recur, so that many treatments might be necessary both by radium and diathermy.

In the nasal sinuses and antrum there was a great variation in the types of growth. The commonest was a cylindrical carcinoma of the adeno-carcinomatous type. For practical purposes all the tumours were malignant, but in very early stages some caused little trouble, so that the true diagnosis was often overlooked. They tended to recur locally, but glandular involvement was late, and metastasis took place only in the last stages of the disease. Surgery alone had given very unsatisfactory results. With surgery, diathermy, and radiation the results had undoubtedly improved.

For the borderline group of cases, without metastasis, preliminary treatment with *x* rays was advisable, followed by a biopsy through the inferior meatus or the canine fossa. If malignancy was established, the next essential step was to provide adequate drainage and exposure, so that the limits of the disease were shown. As a method of approach, he preferred the palatal route, which gave the best drainage, offered the best means of inspection, and caused no external deformity, defects in speech and swallowing could be easily repaired later by a watertight denture. This method gave access to the antrum, nasal fossa, the higher ethmoidal cells, and the sphenoidal regions. The removal of the obvious part of the growth could be effected by diathermy, but in most cases this could only be a partial removal, and it was necessary to treat the peripheral extensions with radiation. Either a large dose of radium could be inserted immediately, or the wound could be left open for a week, and the cavity then treated with radium, in split doses, for a prolonged period, by means of a plate so moulded as to fill the cavity, carrying on its outer surface the requisite quantity of radium in small needles. This apparatus could be worn for six or eight hours daily, until the whole cavity was completely covered with a fibrinous film. In the inoperable group of cases it was questionable whether any treatment should be attempted, but in rare instances, where the growth had not extended too widely into the zygomatic fossa, *x* rays might afford palliative relief.

Almost all forms of sarcoma met with in other parts of the body were to be found in the nasal sinuses, and varied greatly in malignancy. Biopsy was an essential preliminary to treatment, and was safe after a small dose of *x* rays. For the myeloid and fibrous type, which grew very slowly and metastasized rarely, surgery was the best treatment. For chondrosarcoma, osteosarcoma, and myxosarcoma, more uncertain in their course, a combination of surgery, diathermy, and radium was indicated. In the fairly large group of round- and spindle-celled sarcoma, highly malignant, surgery was fraught with great danger. Sometimes the growths were so sensitive that they disappeared completely with *x* rays and surface radium; this treatment should always be tried first. Even in cases where radiation failed, it was seldom possible to excise the whole diseased area. The results with sarcoma had been very much better than with carcinoma.

The Nasopharynx

The commonest tumour of the nasopharynx was carcinoma. Most of the growths in this region were highly malignant; usually they were far advanced before the patient sought advice, and the disease had invaded the base of the skull and the bones at the back of the nose. Metastases in the glands occurred earlier with carcinomas than with sarcomas. Radiation should be applied before trying to confirm diagnosis by a biopsy. Surgery here was useless and dangerous. To deliver an adequate radiation dose to so deep a situation as the base of the skull, intense *x* rays should first be given, followed later by

supplementary local treatment with radium. This latter might be applied either in the form of a suitable tube, containing 50 mg., well filtered with 2 mm. of platinum, drawn up into the nasopharynx through the mouth, and retained by strings passed through the nose for twenty-four to forty-eight hours; alternatively, tubes could be passed through the nose, the disease being treated with split doses for a week or longer until the requisite dose had been administered. Even if the growth was highly sensitive, and disappeared rapidly, the maximum treatment that was safe should always be given. The total dose might vary from 1,500 to 3,000 mg. hours, according to the extent of the growth. Severe reactions might result from the treatment, but these were unavoidable. Even after the acute inflammation had subsided, the healing of the tissues was very slow, and radium necrosis was common. Although these growths were serious, the prognosis of sarcoma was not hopeless. Long-standing cures had been reported, and great prolongation of life could be expected if the treatment were given early, before the glands were affected. On the other hand, Mr. Harmer could find no records of long-standing cures of carcinoma.

The Tonsil and Mesopharynx

Carcinoma of the tonsil was so malignant that simple removal with a knife was dangerous, and ought never to be attempted. The lecturer had used diathermy for many cases, but always in combination with radiation. Most surgeons were agreed that some form of radiation was essential, but it was difficult to decide what was the best method of delivering an adequate dose. At the Paris Radium Institute x rays or distance radium was the method of choice. The lecturer's own view was that the primary lesion should be treated in most cases with needles, and any remaining induration with the diathermy knife. In all cases the neck should be treated with massive irradiation, part of the dose to be given before and part after dealing with the primary lesion. Block dissection should rarely be undertaken; when employed, needles or seeds should be placed in the wound. The results of all the different methods of treatment were still unsatisfactory, but with further research the radiation treatment of new growths in this situation might give results which to-day were impossible to forecast. Sarcoma of the tonsil was much rarer than carcinoma. Almost all surgeons were agreed about the risks of surgical intervention, and it had been noted that the biopsy often failed to give a definite diagnosis. The treatment was unquestionably radiation, either x rays only, or x rays followed by radium. Such statistics as he had been able to collect showed that far better results could be obtained by irradiation of sarcomas than of carcinomas in this region.

Cancers of the Palate, Cheek, and Other Situations

The majority of growths in the palate and cheek were squamous-celled carcinomas; less common were endotheliomas and sarcomas. Growths in the buccal mucosa had a more serious prognosis than palatal growths, and the prognosis of lesions in the soft palate and uvula was more serious than in the hard palate. The primary growth should be treated before the glands, except in very rapidly growing tumours, in which a pre-operative x-ray application to the primary and lymphatic area should always be given. The growth should be treated afterwards by needles, seeds, or surface radium, since x rays alone could not be relied upon to destroy it. For the hard palate a denture carrying radium was a simple method of giving surface treatment, and for the protection of the tongue it should be lined on its under surface with 1 mm. of lead. If complete healing was not obtained within a reasonable period, the induration should be excised by diathermy.

The decision as to treatment of the glandular area presented many difficulties. If no glands were found on examination, and the growth was not of a very virulent type, the neck might be left untouched, though it must be examined periodically. Small, movable, unilateral glands should be removed, preferably after preliminary radiation. Large, fixed, or bilateral glands were always inoperable, but the disease could be arrested by a combined treatment with x rays and radium or either alone. The results on the whole were good.

The lecturer touched upon endothelioma, which was of not uncommon occurrence in the palate, pharyngeal wall, nasopharynx, and neck. It could never be trusted to remain quiescent, and the sooner it was removed the better. Endotheliomas in their early stages had a dense fibrous capsule, and were easy to enucleate. The small area of tumour adherent to the surrounding tissues, which was the base of the attachment, should be cauterized to prevent local recurrence. The treatment was pre-operative x rays, followed by enucleation of the growth a week later, and the insertion of radium. Transitional cell carcinomas and lympho-epitheliomas deserved consideration because of their high malignancy and remarkable susceptibility to radiation; they might commence in the tonsil, base of tongue, nasopharynx, larynx, or perhaps oesophagus.

Conclusions

At each stage of his lecture Mr. Harmer described illustrative cases, and gave statistics of survival for the cases treated in his own unit and collected from other workers. The results in his own clinic, out of more than 400 cases, showed 19 per cent. of cases of carcinoma surviving, 50 per cent. of cases of sarcoma, and 47 per cent. of cases of endothelioma. A large proportion of his carcinoma cases were inoperable. He believed that there was a great future for radiotherapy, if the treatment was properly handled, but it was necessary to have special clinics, richly endowed, vigorously supported by those in control of radium, and staffed by groups of expert specialists. Radium had not made the surgery of cancer of the throat easier, but more complicated. He doubted the wisdom of a surgeon employing radium without the help of a group of experts. Equally the patient ought not to be handed over to the pure radiotherapist who had no clinical knowledge of the disease. With careful treatment, relief could be afforded by radiation to a large proportion of advanced cases of cancer. It was safer to treat the virulent types of cancer with radiation than with surgery alone; even early cancers might confidently be treated by radiation by experts. There was reason to believe that external irradiation was necessary in nearly all cases before local treatment with radium, but it was not clear whether x rays or large quantities of radium were best for this purpose.

A representative meeting of bio-physical assistants was held in London on November 4th, when the question of constituting an Association of Bio-Physical Assistants was discussed. It was agreed that such a society was necessary, and the following resolution was proposed and carried unanimously: "That an Association of Registered Bio-Physical Assistants be and is hereby constituted for the purpose of (*a*) advancing the study and practice of physical methods, and making available to the public greater facilities for such methods through the medium of registered workers; (*b*) to promote the welfare of bio-physical assistants in their professional capacity; (*c*) to co-operate as required with other recognized bodies for the achievement of the above ends." An organizing committee was appointed for the purpose of registering the association and drawing up its constitution, etc.

HEALTH OF THE SCHOOL CHILD

SIR GEORGE NEWMAN'S REPORT

[First Notice]

The annual report of the Chief Medical Officer of the Board of Education (Sir George Newman) for the year 1930* covers a wide range of subjects. Perhaps one that is most pressing is noted at the outset. It is stated that: Year after year in these reports attention has been drawn to the physical condition of children as we find them when first they enter the elementary schools. The defects which commonly develop during the first five years of life are almost entirely preventable, and, in theory, there is no reason why the entrants to school should not consist, with few exceptions, of normal healthy children. The fact remains, however, that some 20 per cent. of these entrants require treatment of some sort, while a very considerable proportion in addition, though not immediately requiring treatment, show some undesirable deviation from the normal. It has for a long time been realized that most of these defects have arisen between the ages of 2 and 5 years. Maternity and child welfare schemes have, on the whole, made fairly adequate provision for the care of children up to the age of 2 years, but there are comparatively few areas where the same care and supervision are available during the three succeeding years. Even in those areas where they are available full advantage is not always taken of them. The average mother realizes her need for skilled advice in the care of infancy, but she often considers herself quite competent to diagnose and treat the ailments of the "toddler" stage.

Medical Examination in Schools

During the years of school life the provision is excellent. The statutory requirements of the Board call for a medical examination of each child as soon as practicable after entering school, at or about 8 years, and before leaving school. The ultimate aim of these inspections is not only the detection and treatment of disease and defect, but also that of advising on the conditions necessary to create and maintain all-round healthiness. Comment is made that local reports do not sufficiently indicate the general state of health of the children. A tale of defects found does not indicate this. At every examination the question should be asked, "Is this child developing according to the plan Nature has mapped out for him?" The question is difficult to answer, for it does not depend upon averages of height or weight, of alertness or mental attainment, or upon any other average standards, *but upon an estimate of the whole individual.* Inspection will, in the majority of cases, enable the medical officer to pass a child as normally healthy, but in a substantial minority it will not be possible to do this with certainty. These children will be submitted to a short period of general observation and examination, specially directed to such matters as evidence of chronic fatigue and of malnutrition.

It is also a matter of importance that the children at medical inspection should be accompanied by a parent, usually the mother. It is no exaggeration to say that where the attendance of the parents is exceptionally low there is something wrong, unless, indeed, the area is one where the local industries depend largely on female labour. Though the medical officer's primary object is to assess the physical condition of the child, it is of equal importance that he should be able to estimate the attitude of the mother. Is this parent to become an ally or not?

During the past year the number of children inspected at routine and special examinations totalled two and three-quarter millions, or 55·4 per cent. of the average attendance. Defects of vision head the list of defects found, closely followed by enlarged tonsils and adenoids. Skin diseases follow a long way behind. The percentage of children found to be suffering from definite defects (excluding dental disease and uncleanliness) requiring treatment was 20·9 per cent. Reference to the returns of past years do not show much variation, though reports from some areas are most promising. In Sunderland the percentages of those requiring treatment have been halved in the space of seven years. In some directions there has been indubitable success; the striking reduction of ringworm of the scalp which is invariably brought about in the areas of authorities which provide x-ray treatment as a routine measure; for example, in Bristol there has been a fall in nine years from 183 to 8 among some 60,000 children. In Hull the cases used to average 150 a year; last year there were only 93. But it is disappointing to learn that over 700,000 out of five million school children were found to be unclean. Over fourteen million examinations were made by the school nurses, and in 1,069 cases parents were prosecuted. It is suggested that the work of the school nurses would be made more effective if there were a more frequent resort to the weapon of prosecution. Dirt often means disease, and cleanliness engenders self-respect. By insisting on cleanliness parents and children learn that they themselves have an important part to play in the care of the body; that the school medical service is not a scheme for doing work for the children, but an agency which seeks to help those who help themselves.

Speech Defects

A considerable number of local authorities have established classes for the treatment of stammering and other speech defects. A child who leaves school without having acquired the power of expressing himself in writing may be unemployable, and is evidence of the failure of the educational system, but inability to speak distinctly is an even greater reflection on the system if the defect is remediable. There is an imperfect realization of the results obtained by a skilled teacher. School medical officer reports show that the degree of improvement resulting from such teaching is well worth while, though none of them is so blind to facts as to claim 100 per cent. of cures. At one centre the after history of 68 cases was investigated: 12 were apparently cured, 38 were much improved, and with only occasional hesitancy if excited; 13 were improved but having more or less frequent lapses; and in 5 the condition was practically unchanged.

Educational Strain on Eyesight

Reports on the children in secondary schools call frequent attention to the prevalence of defective vision. The London report says:

"Considering the higher proportion of girls than of boys wearing spectacles, and that the number wearing them increases between 12 and 15, and that notwithstanding this the visual acuity of the girls is markedly less than that of the boys, whilst also visual acuity declines in both during secondary school life, there appears to be no escaping the conclusion that education imposes injurious strain upon the eyes, greater in girls than in boys. Of the men in training colleges 70 per cent. were able to pass the vision test, 26·4 per cent. of those examined wore spectacles. Among the women 72·2 per cent. passed the vision test, but 33·5 per cent. were wearing spectacles."

The School Dental Service

It is an acknowledged fact that an adequate scheme for dental care during school life is one of the most valuable parts, from the point of view of health, of the school medical service. There has been a considerable increase in the number of dentists appointed for the work;

* The Health of the School Child. Annual Report of the Chief Medical Officer of the Board of Education for the Year 1930. London: H.M. Stationery Office. 1931. (2s. net.)

it is now 741, as against 481 last year. The amount of conservative work has increased, both absolutely and relatively, the number of fillings averaging 68 per 100 children treated, as compared with 65 in 1929. The percentage treated during the past four years has been 58.1, 58.4, and 58.5, while in 1930 it was 63.4. It may be looked upon as a reflection on our educational system that after fifty years of universal education a considerable proportion of parents refuse dental treatment for their children when skilled treatment is provided free of cost. Since in more educated classes dental treatment is sought after and obtained at much cost, we may infer that those who refuse treatment do so because they fail to understand the importance of sound teeth in the maintenance of health and the damaging effect of bad teeth.

Reference is made to the work of Mrs. Mellanby and others concerning the possibility of the prevention of dental disease by dietetic measures. As recorded in these columns on October 3rd (p. 615), a well-controlled experiment was carried out in a Birmingham residential institution: 332 children were under observation, of an average age of 9 years. One group was given cod-liver oil or irradiated ergosterol, the other oily food that did not contain vitamin D. At the end of two years there was a significant retardation of the progress of caries of the permanent teeth in the vitamin group in each investigation as compared with the other groups. There was approximately one-third less caries. The hope that dietetic measures may check the incidence of dental disease is reasonable, but it still awaits the confirmation of wider experience. The influence of the teachers in the improvement of the condition of the teeth of the children is commented upon favourably. More than half the battle has been won when the children have learnt to be interested in and proud of their teeth, and desire to keep them whole and not unattractive.

Ireland

Annual Meeting of the British Medical Association, Dublin, 1933

The Executive Committee appointed to make arrangements for the annual meeting of the British Medical Association to be held in Dublin in July, 1933, met recently in the Royal College of Physicians, Dublin, with Professor T. G. Moorhead in the chair. As it is expected that more than a thousand doctors from Great Britain and other parts of the world will attend the meeting—the first to be held in Dublin for almost fifty years—it is considered essential that arrangements should be made without delay. Seven committees have been appointed for this purpose.

Irish Free State Medical Registration Council

The autumn session of the Medical Registration Council had held on November 3rd at the Council's office, the pr per Fitzwilliam Street, Dublin. There were present: more si sident (Dr. Denis J. Coffey), Mr. William Doolin, growth sh Dundon, Dr. Edward Magennis, Dr. James N. very rapidly Henry F. Moore, Dr. Thomas Gillman *x*-ray applicat Robert J. Rowlette, Dr. Stephen Shea, should always be Stoney, and the Registrar, Miss Eileen E. afterwards by ne less of the session included correspond- *x* rays alone could p istry of Industry and Commerce, and the hard palate a den lwives Board, Saorstát Eireann, on method of giving surface Rules arising from the Midwives of the tongue it should be was approved by the Council. 1 mm. of lead. If comple medical examinations of the ies having been initiated at the May session, 1931, a number of such examinations were visited during the summer examinations. Arrangements were made to complete the visitation at the winter examinations this year. Other routine business included matters arising under the procedure of registration, certificates of death, and the consideration of penal cases.

Dublin University Biological Association

At the annual opening meeting of the Dublin University Biological Association, held in Trinity College on October 31st, Dr. A. H. Davidson (president-elect) read a paper entitled, "Caesarean section: its history and present status." Dr. Davidson traced the history of the operation from the earliest times, and pointed out that it was attended by a very large mortality during the eighteenth and nineteenth centuries, and was only used as a last resource. For some time it lost favour, but later regained popularity amongst obstetricians. Its rehabilitation was greatly assisted by the attitude of the Roman Catholic Church. It really began to have a definite place in obstetrics from the year 1880 onwards. The speaker next discussed the position of the operation in modern obstetrics, and quoted collected statistics of large numbers of cases in 1911 and 1921 to show that it was gradually becoming safer. This was leading to a swing of the pendulum in the opposite direction, and the present tendency, especially in America and on the Continent, was to perform the operation rather too often. He deprecated this attitude. He discussed the position held by Dublin in the world of obstetrics, and the attitude which it had adopted towards the operation, describing this as one of extreme conservatism, which led to its performance only when necessary in the interests of mother and child. Dr. Davidson then showed a cinematograph film of a lower segment Caesarean section performed recently at Dr. Steevens's Hospital. Mr. L. C. Rivett (Queen Charlotte's Hospital, London), in proposing a vote of thanks to the president-elect for a most attractive paper, said that he had always been interested in this operation. Dr. Solomons reported on 161 Caesarean operations at the Rotunda during the first four years of his Mastership. Of these 85 were performed by the lower segment route with one death, and this case was complicated by tumours. Caesarean section, he said, could be repeated many times. Professor T. G. Moorhead, P.R.C.P.I., proposed that the "Dublin University Biological Association is worthy of the support of all the medical students in the University of Dublin." Sir William de Courcy Wheeler, in seconding the resolution, which was carried with acclamation, said that, having heard Dr. Davidson's address, he was more convinced than ever before of the value of the Association. He deplored the fact that in this era of specialization Dublin was handicapped, so far as the training of specialists was concerned, by its obsolete system of multiple small hospitals. In Dublin there was a hospital at the corner of almost every street, each one equipping itself to duplicate the work of its neighbour. Now that the voluntary system of finance was dead, it was difficult to know what would happen to these hospitals when the sweepstakes fountain ceased to flow. It was well for the profession to realize that the Government already had its finger in the pie, and that, for good or evil, the hospitals were heading towards State control. Sir William asked whether it was too late for a great scheme of amalgamation such as was agreed upon a few years ago. At that time there was a hope of money, but none was forthcoming; now the money was there. The president (Dr. L. Abrahamson) distributed the medals as follows: Daniel John Cunningham Medal, Laurence Kolb; John Mallet Purser Medal, Horace Donagh O'Brien; Dublin University Biological Association Medal, Albert A. Cunningham.

Milk Supply for Infant Welfare Centres

At a meeting of the Belfast Public Health Committee the medical superintendent officer of health reported that the death rate for the week ended October 24th, was 11.1, that from the principal zymotic diseases being 0.3, as compared with 10.6 and 0.5 for the previous week, and 12.1 and 0.7 and 13.9 and 0.6 for the corresponding period of last year. The committee recommended the council to adopt by-laws regulating the sale of ice-cream. These by-laws deal with the construction of premises, and include precautions for protecting food against infection or contamination, and provisions for the inspection of premises and the hours during which they may be kept open. The chairman reported that a complaint had been made to him that during past months the supply of milk for child welfare centres in the city had decreased, and that over the same period the administration costs had increased considerably in consequence of the salaries of additional doctors and nurses. In his opinion this was defeating the object of the scheme, which was intended to provide milk for the poor children of the city. Too much money, he contended, was being spent on professional services, and the centres were gradually changing from child welfare centres to adult welfare centres. He suggested that better service would be rendered to the children with the limited supply of money available by increasing the milk supply and reducing the number of officials in connexion with the scheme.

Belfast Health Statistics

Referring to tuberculosis, Dr. Thomson states that tubercle-infected milk is responsible to a great extent for surgical tuberculosis in children ; he adds that the amount of tuberculosis in cattle is so great that it would be economically impossible to slaughter all the infected animals. It is reported that 25 per cent. of the dairy cows kept in sheds suffer from tuberculosis, and the latest Royal Commission states that the milk of cows suffering from tuberculosis frequently contains tubercle bacilli. In Dr. Thomson's opinion the only hope at present—when some 8 per cent. of milk samples are found to contain tubercle bacilli—is to use milk from cows which have passed the tuberculin test or to drink pasteurized milk. His reason for preferring pasteurized milk to Grade A (T.T.) milk is that the heating process in the former destroys any scarlet fever or diphtheria toxins. He further suggests that the disease should be made notifiable in all its stages instead of, as at present, only in cases where germs are found in the sputum. Mention is made of the existence of many overcrowded and ill-ventilated schools, and the necessity for more accommodation for tuberculous school children is stressed. At present Whiteabbey provides accommodation for sixty-five such cases, but room is needed for at least one hundred. In regard to other diseases in the city it is gratifying to note that scarlet fever is diminishing. Although 1,132 notifications were received, there were only seven deaths, the disease in most cases being of a mild type. An increase in notifications of diphtheria was recorded (618 cases), and twenty-two deaths occurred from the disease. Stocks of diphtheria antitoxin are kept at six depots in the city. Deaths from cancer totalled 424. Thirty-two cases of typhoid were notified, and two deaths from the disease were registered. Purdysburn Fever Hospital received 2,053 cases during the year, and at the municipal laboratory 12,070 specimens were examined. Incorporated in the report is a special report on the tuberculosis department by the chief tuberculosis officer, Dr. Trimble, who gives an account of a tour of investigation through Canada and the United States.

Scotland

Aberdeen Nerve Hospital

The Wellwood Nursing Home, for early mental cases, situated near Cults, Deeside, was formally opened on October 31st by Sir Ashley W. Mackintosh, emeritus professor of medicine in Aberdeen University. In performing the ceremony, Sir Ashley said that the whole trend of modern medical science was in the direction of early treatment and, so far as might be, of prevention of disease. There was no branch of medical work in which this attitude was more important than in dealing with mental cases, particularly among the young, and the institution which they were opening that day would be a valuable contribution towards this end. He was afterwards presented with a gold match-box, as a memento of the occasion, by Mr. George Robb, on behalf of the directors of the Royal Mental Hospital, Aberdeen.

Peterhead Water Supply

The Water Committee of Peterhead Town Council recently considered a joint report on the water supply of this burgh prepared by the medical officer of health and city engineer for the city of Aberdeen. The report states that in the last week in September various complaints were made by residents that, when warmed, the water supplied by taps had a smell of fish. Samples taken proved that the water was of good quality both chemically and bacteriologically, but that it contained an excessive quantity of infusoria. It had been decided that water should be supplied to the town direct from the reservoir, that the condition of the filter beds should be investigated, and that a preliminary course of chlorination of the beds should be adopted. It appears that the filter beds have been in operation for over twenty years, and that the time is now opportune for their complete renewal with fresh materials. It is also recommended that domestic storage cisterns should be thoroughly cleaned out, and that every morning before use the water in each house should be run for three or four minutes. The report contains the somewhat surprising assurance that the water is fit for drinking purposes in every respect.

Fire in St. Andrews Laboratories

A destructive fire, which caused damage estimated at £7,000, broke out on November 3rd in the natural philosophy and chemistry departments of the United College, St. Andrews. A good deal of valuable apparatus was destroyed, and some rooms were completely gutted. The fire appears to have originated in connexion with the central heating arrangements, and is supposed to have been burning for about an hour before it was observed, about 4.15 a.m., by students residing in the neighbouring St. Salvator's Hall. The rooms of the research students were completely destroyed. Some valuable apparatus of historical association, used by the famous Gregory and others, fortunately escaped damage. In the chemistry department a lecture room, research laboratory, and the museum all suffered considerable damage.

Certification of Blind Persons

A memorandum in relation to future administration connected with the welfare of blind persons has been issued by the Department of Health for Scotland. The memorandum refers to the recent establishment in the cities of Edinburgh, Glasgow, Dundee, and Aberdeen, of regional clinics for the examination of persons claiming to be blind, and lays down that these clinics must be used

as far as practicable by local authorities in Scotland in determining whether a person is or is not blind, for the purposes of benefit under the Blind Persons Act, 1920. The principles enunciated by the meetings of the ophthalmic surgeons, convened by the Department of Health and reported to the Department, are to form the basis for future certification. A standard form of medical certificate has been drawn up for use in this connexion, and it is recommended that this certificate should be signed by two ophthalmic surgeons. It contains, in addition to the information regarding the fact of blindness, a statement whether the applicant, if a child, is, though not blind, likely to become blind and likely to benefit by attendance at a sight-saving class. The recommendations of the examining surgeons, in regard to eye treatment, are also to be recorded, and local authorities are desired to make arrangements to secure that any such treatment shall be duly obtained. The value of the regional clinics to local authorities is also emphasized in the memorandum. These clinics enable local authorities to satisfy themselves that the numerous benefits now afforded to blind persons will be applied only to those who are entitled to them. Such benefits include public assistance, elementary or technical education, social services of voluntary agencies, etc. It is suggested that all registered blind persons, or at least all doubtful cases, should be re-examined.

Alcohol in Child Life

The first lecture of a short series dealing with the relations of alcohol to civic life, under the auspices of the Scottish Temperance Alliance, was delivered on November 3rd by Dr. E. M. Pringle, assistant clinical medical officer for child welfare under the Edinburgh Corporation. The lecturer said that alcohol was one of the three racial poisons which damaged the life stream at its source, and was responsible not only for stillbirths and the birth of many debilitated children, but for a large proportion of the infant mortality, which showed a progressive fall in accordance with the progressive reduction in alcoholic consumption. Overlaying of infants was a common result of alcoholism, which had been reduced recently in Edinburgh by the provision of cradles of cheap construction. In 1907 there had been 907 deaths of young children (34 from overlaying); in 1917, 604 (3 from overlaying); and in 1927, 606 (2 from overlaying). Dr. Pringle further traced the relationship between infant mortality in different wards of the city and the number of licences existing in these wards as well as the varying housing conditions. In Morningside ward, where the licences numbered 15 (1 to 1,361 persons) the infantile mortality was 13 per thousand, while in Canongate, with 40 licences (1 to 521 persons), the infantile mortality rose to 108 per thousand. In Scotland the expenditure on alcoholic liquor was £6 10s. per head per annum, while only £2 1s. was spent on milk.

New Infectious Hospital for Paisley

At a meeting of the Paisley Town Council on November 6th it was decided to proceed with a scheme for a new hospital for infectious diseases, and a committee was appointed to select a site. It was pointed out at the meeting that the present hospital was not satisfactory, because patients with different troubles were treated occasionally in the same ward. The new hospital is estimated to cost approximately £100,000.

District Nursing in Scotland

At the quarterly meeting of the Scottish Council of the Queen's Institute of District Nursing, held in Edinburgh on November 3rd, it was intimated that during the previous quarter, 26 nurses had completed district training and 13 midwifery training, and that these had been appointed district nurses in various parts of Scotland, chiefly in the Highlands and Islands. Twenty-two resignations of nurses were received; retirement, other work, and marriage being the chief causes. In regard to the nursing work in the city of Edinburgh, it was stated that 1,061 new cases had been treated during the quarter, and that the nurses had paid a total of 42,244 visits.

England and Wales

Mortality Rates in Birmingham

Dr. H. P. Newsholme, medical officer of health for Birmingham, provides in his annual report for 1930 a good example of the way in which such publications can illustrate the practical working out of public health schemes. Illuminating comments are appended to the various tables, and details are given of the progress of various institutions. The death rate during the year under review was 10.8 per 1,000, the lowest ever recorded in that city. In the earlier part of the period 1871–1930 the Birmingham death rate was above that of England and Wales; in later years the position has become reversed, with the exception of 1929, when the figure was slightly higher owing to the serious influenza epidemic. The rate compares favourably also with those recorded in most of the other great cities. Thus it is below those of London, Glasgow, Liverpool, Manchester, Leeds, and Edinburgh, and only slightly above that of Sheffield. As usual, the mortality among males was notably higher than among females, the number of deaths being 5,515 against 5,098. More than half the deaths occurred last year in persons below the age of 65, while considerably more than a quarter died before the age of 45; Dr. Newsholme concludes, therefore, that there is still considerable scope for public health enterprise. Among school children the principal causes of death were accidents, diphtheria, and rheumatic fever; while between the ages of 15 and 25 the most serious cause was tuberculosis, accidents coming second and heart disease third. Of the total number of deaths at all ages and in both sexes (10,613), no fewer than 1,220 occurred between the ages of 25 and 45, representing a very grave waste of effort in education and training. These deaths were caused principally by tuberculosis, pneumonia, and heart disease. After being stationary for several years the mortality from cancer again showed some increase, improved diagnosis being partly responsible, and also the fact that the proportion of persons of advanced age is undoubtedly increasing. No evidence was obtained to indicate that this disease was more prevalent in the older and less healthy sanitary districts. The death rate from respiratory diseases is slightly higher in Birmingham than in England and Wales, which is not the case as regards cancer or morbus cordis. The mortality in the central wards of the city was nearly twice as high as in the outer ring; in the body of the report information is given as to the steps which are being taken to improve matters. For example, in addition to increasingly strict control of factory chimneys, the Midlands Joint Advisory Council for Smoke Abatement has co-operated with the committee of the Birmingham Central Technical College in establishing a training course in smoke prevention for stokers and engineers. The first course given during the spring in this connexion consisted of a series of five lectures and four demonstrations, which were well attended and proved highly successful; a more detailed course is being held during the autumn. Observations each month on the atmospheric impurities carried down in the rainfall have

shown that the soot deposit in the centre of the city is about six times greater than in the suburbs. A five year programme of clearing unhealthy areas has been proposed by the city council. The anti-tuberculosis campaign—of which full details are given—makes special provision for preventing infection by the isolation of advanced cases, a large number of beds for their care and treatment being now available. It is recognized that the risk of infection from this type of patient usually increases during the last six months of life.

Radium at London County Hospitals

After a consideration of the existing radium units and the work done, the Central Public Health Committee has reported to the London County Council that radium treatment is available for all patients in the Council's hospitals for whom such treatment is indicated, and that no additional facilities are required at present. Treatment by radium is now being carried out mainly at Lambeth (General) Hospital, the North Western (Fever) Hospital, Hampstead, and Queen Mary's Hospital for Children, Carshalton. Lambeth Hospital has 511·64 milligrams, together with an outfit for producing deep *x* rays. At the North Western Hospital, where cases of carcinoma of the uterus are treated by radium—91 such cases last year—334 milligrams are available. St. Mary's Hospital has only 15 milligrams, used practically entirely for the treatment of tuberculous adenitis. At other hospitals under the Council's control, radium treatment is carried out to a limited extent by radium needles or radon seeds. There is no evidence of an unsatisfied demand for radium treatment in the Council's hospitals, nor have the medical superintendents experienced any difficulty in obtaining through some other institution, radium treatment for any patient requiring it. A few patients have been treated in the hospitals by means of hired or loaned tubes, but it is felt that this practice should be discouraged, because the technique of treatment demands highly specialized training and experience, and, except in very special circumstances, all patients should be treated in units possessing equipment and staff adequate in all respects. A further report on the question of treatment by radium and deep *x* rays is to be submitted in a year's time.

Medical Staff of L.C.C. Hospitals

It is proposed by the London County Council to make in the twenty-eight general hospitals under its control eighteen additional positions of permanent assistant medical officer. This decision has been made after taking into account various factors, such as the necessity that the staff of each hospital should be sufficient for ordinary working, for the proper medical care of every patient, and for the keeping of adequate records; also the requirement that the staff shall have adequate weekly leave. It was found on a review of the situation that the staff at sixteen hospitals should be strengthened without delay. Four temporary assistant medical officers and two clinical assistants will be replaced by the new appointments. The rate of remuneration for the assistant medical officers will be £250 a year, plus residential emoluments (or a non-residential allowance of £150 a year in those cases in which residential accommodation cannot be provided). These and other proposals in connexion with some of the special hospitals represent a stage in the policy of replacing temporary staff gradually by permanent staff with the object of securing greater efficiency and economy. It is hoped also by this increase of the permanent staff, and by close supervision of the annual leave arrangements at the hospitals, and the most economical use of the services of locumtenent medical officers to effect a saving of approximately £8,500 a year in the current cost of the employment of such staff. At present, the total annual cost of the employment of such locumtenents during the absence (owing to illness, holidays, or other reasons) of the permanent staff is £17,700.

Nuttall Portrait Fund

Professor G. H. F. Nuttall, M.D., F.R.S., retired last month from the Quick chair of biology at Cambridge, which he held for twenty-five years, and an influential committee has been formed to raise funds for the presentation to him of his portrait. A circular letter addressed to his friends and admirers recalls the conspicuous services rendered by Professor Nuttall to preventive medicine in the fields of bacteriology, immunity, hygiene, and parasitology, by his personal researches and encouragement to others. "In addition he has founded and edited two of the leading journals concerned with hygiene and parasitology, and by his efforts has obtained funds to found the Molteno Institute of Parasitology at Cambridge. As a result, there has arisen a school of research workers now scattered throughout the world, many of whom gratefully acknowledge the inspiration which they have derived from his teaching and example." Contributions, not exceeding three guineas, should be made payable to the honorary treasurer, Dr. C. M. Wenyon, but sent to the honorary secretary, Dr. Edward Hindle (32, Belsize Avenue, Hampstead, N.W. 3), and cheques should be crossed "The Nuttall Portrait Fund."

Correspondence

SUSCEPTIBILITY OF CELLS TO HORMONIC INFLUENCE

SIR,—Like Mr. T. C. Clare (November 7th, p. 870), I also regard tissue cell sensitivity to hormonic influence as a matter of fundamental physiological importance. It can, I think, be shown to occur in other conditions beside that of cancer. In the *Journal of Genetics* (February, 1914) I described a case of unilateral distribution of plumage, and other secondary sex characters, in a pheasant. In this case the asymmetric distribution could not be explained by hormonic influence alone, because the male or female sex hormone must necessarily be distributed equally to both sides of the body. The suggestion was made that the unequal distribution in this case depended on a difference in tissue susceptibility, or capacity of response, to the hormonic stimulus on the two sides of the body. In like manner it may well be that malignant cells differ from normal cells in susceptibility to hormonic influences of various kinds. May I at the same time express my appreciation of the value and suggestiveness of Dr. Susman's paper published in the *Journal* of October 31st.—I am, etc.,

Leicester, Nov. 8th. C. J. BOND.

THE PITUITARY IN THE ETIOLOGY OF CANCER

SIR,—The article by Dr. Susman concerning post-pituitary gland in malignant disease tends to confirm certain clinical experiences. My object in writing this note is to suggest that placental extract be combined with the post-pituitary. Most of my cases have been hopeless, but in one case of malignant disease of the hypopharynx with partial laryngeal paralysis the tumour has vanished after weekly injections; the paralysis, however, remains. The injections are made around the tumour. Pain and reaction may be severe, the severity seeming to presage improvement. I presume that human placental extract

may be more helpful still ; it seems impossible to obtain a satisfactory preparation in this country. There appears to be no doubt whatsoever that shrinkage occurs with pituitary extract alone injected *around the growth*.—I am, etc.,

Manchester, Nov. 4th. WM. WILSON.

CONVALESCENT SERUM IN PROPHYLAXIS OF MEASLES

SIR,—In your issue of November 7th you refer to the report of the Central Public Health Committee of the London County Council, in which it is stated that an epidemic of measles is expected in London during this autumn and winter. Various statistical data as to the number of children who have been affected in previous epidemics and the mortality at different age periods are given, and mention is made of the fact that such epidemics of measles cannot be prevented, but that their effects can be mitigated.

If one may judge by the abstract which you give in the *British Medical Journal*, and which was also given in the *Times* of November 2nd, among the measures which this report of the Central Public Health Committee recommends in order to reduce to a minimum the number of complications, no reference is made to the use of convalescent serum in the prevention of the disease in individual cases. This omission evidently resulted in the publication in a leading article in the *Times* of November 3rd of the statement that measles, "the most prevalent of all the diseases of childhood, remains almost wholly unpreventible." It would be regrettable if this idea were to become at all widespread, and particularly among the members of the medical profession, for since Nicolle and Conseil, in 1916, first succeeded in protecting children from measles by injection with convalescent serum, many observers in many countries have demonstrated the great value of convalescent measles serum in prophylaxis.

As a matter of fact, this method of preventing measles has been in use at the Great Ormond Street Hospital since 1928, and at the suggestion of the Ministry of Health our existing scheme for obtaining a larger supply of serum with the co-operation of Dr. R. Massingham of the London Fever Hospital, in order that some might be available for other institutions, was inaugurated. A summary of the results obtained by the use of the serum we have prepared was given by my colleague Dr. Signy and myself in a paper which we read at the Annual Meeting of the British Medical Association at Eastbourne last July (published in the *British Medical Journal*, October 3rd, 1931). Moreover, the treatment is referred to, and with approval, by Sir George Newman in his annual report as the Chief Medical Officer of the Ministry of Health for the year 1930, and, in the report on measles, dated July, 1931, by Dr. Kay Menzies, the medical officer of health and school medical officer of the London County Council. In fact, the last sentence in the Council's report states:

> "It is hoped that in the future concerted measures will be taken with a view to augmenting the supplies of serum, possessing as it does such potential value in the reduction of infant mortality during epidemics of measles."

In view of the facts which I have here brought forward, and of the acknowledged value of this method in various Continental countries and America, it seems to me a pity that in an official warning, such as the one to which I refer, no mention whatever is made of the real value of convalescent serum in the protection of young children. In my opinion we should take every possible measure to reduce the incidence of measles among children under the age of 3, because by so doing a considerable number of lives will be saved, and in these days of a greatly lowered birth rate this is a matter of no small importance.

During the past week the Great Ormond Street Hospital had requests from four different sources for several hundred doses of convalescent serum. Unfortunately the supply available is now so small that only a small fraction of these could be satisfied. It has been shown at Birmingham and elsewhere that it is not necessary for the blood to be that of a recent convalescent, but that any adult who has previously suffered from an attack of measles could furnish a useful serum. That being the case it should be possible by proper organization to arrange that a sufficiency of prophylactic serum be available in order that as many children as possible under the age of 3 or even 5 years be protected during an epidemic period. Such a scheme has already been working in Paris and other cities for several years ; it should surely be possible to organize such a scheme in London and the larger provincial cities.—I am, etc.,

London, W.1, Nov. 9th. DAVID NABARRO.

RHEUMATOID ARTHRITIS

SIR,—Your correspondent Dr. Graham-Bonnalie stresses an extremely important point, in his letter on the treatment of rheumatoid arthritis (November 7th, p. 871), when he states that "the fault with most forms of treatment, in the active stages of the disease, is that they are too drastic." This is a point which appears to be insufficiently borne in mind by many medical men ordering or applying treatment (both physical and otherwise) to patients who are generally already in a very low state of resistance as the result of their disease.

Dr. Coates, in his excellent letter in the same issue, encourages us to research along therapeutic rather than etiological lines. This, though of necessity often empirical, seems to be the rational plan. My work on transfusion in these cases, which was quoted by "Crippled" (in her second letter), rests on the assumption that the etiology in these cases is *not proven*, but is probably either (*a*) infective, or (*b*) metabolic (endocrine). In the former case antibodies are provided and stimulated ; whilst in the latter case the small amounts of endocrine secretion contained in a large transfusion of normal blood will prove the best stimulus for the glands of the patient to resume activity.

Finally, may I venture to doubt whether Dr. Jordan's explanation of the predominant female incidence of the disease, which he attributes to their greater liability to severe forms of chronic intestinal stasis, contains the whole truth. It would be difficult to explain the remarkable results which are sometimes obtained by means of intrapelvic diathermy (which is believed to stimulate the ovarian glands) if this were so.—I am, etc.,

London, W.1, Nov. 7th. W. S. C. COPEMAN.

PAIN IN THE ARM AND A DEAD TOOTH

SIR,—Dr. Sanguinetti misses my point. I do not advise the removal of teeth, tonsils, or appendices unless clinical experience—of which I have had a good many years, in a good many places—leads me to believe that the removal will be advantageous. But I do insist that, when clinical experience is in favour of removal, we should not hesitate *because* we are unable to "explain" how, why, or in what manner the removal "acts." Equally, when clinical experience leads me to believe—as it generally does—that vaccines will be useless, I insist that we should not give them, merely because a pathologist "explains" to us what he calls their "mode of action." In a word: I appeal to clinical experience, fortified by reason, rather than to laboratory-bred theory, supported by hope or *in*-credulity.—I am, etc.,

London, W.1, Nov. 7th. F. G. CROOKSHANK.

CARDIOSPASM

SIR,—May I be permitted to comment in brief upon Dr. Alfred C. Jordan's letter on cardiospasm in the *British Medical Journal* of October 10th (p. 678)?

Dr. Jordan commences by stating his preference for the name "cardiospasm" as compared to "the humorous one coined by Sir Cooper Perry." He refers, presumably, to the name "achalasia," which is becoming increasingly common in the literature, and which, since it certainly was not proposed by Sir Cooper Perry in jest, must have a humour apparent only to a certain few. Without wishing to suggest that achalasia is the name which will withstand the ravages of time, nevertheless I believe it to be the best of those at present available, since it not only expresses the outstanding feature of the disease, but also overcomes the incongruity of applying the term "cardiospasm" to cases such as Dr. Butler's, "in which there is no actual spasm" (the words quoted are Dr. Jordan's). Even in those cases which show spasm, there is no doubt in my own mind that such spasm is a purely secondary feature. However, it is not my purpose to do more than comment on Dr. Jordan's taste in nomenclature. The point is a small one, and perhaps the fact that "cardiospasm" has the advantages of hoary old age gives it, in spite of its inappropriateness, a Linnaean status.

It is on the question of the pathology of this condition that I wish to take open issue with Dr. Jordan. Dismissing in a very few words all work on this subject, he states that all his cases of genuine cardiospasm go to prove that the complaint is due to three things: (1) the traction of a large, heavy stomach on the cardia; (2) toxaemia of the tissues concerned; and (3) an idiosyncrasy of the individual. Let us examine this tripod of causes on which Dr. Jordan sets the disease. He says that the fact that the stomach is large, in spite of little food entering it, is proof positive that the enlargement precedes the oesophageal trouble. These are rash words. Proof positive in clinical medicine is something for which we all strive, but few, if any, achieve; nor in this case is the promise in any way fulfilled. It is by no means always the case that achalasia is complicated by an enlarged stomach. I myself have had occasion to pay careful attention to this point, not because I believed it to be a cause of the condition, but because I thought that an irregularity of action of the pyloric sphincter might well accompany the achalasia of the cardia. If I failed to find definite histological evidence one way or another, it was because such enlargement was not found in a sufficient percentage of cases. The suggestion that the gastric enlargement must precede the oesophageal disease because, after the onset of the latter condition, little food enters the stomach, is difficult to regard seriously. Many patients in whom the stomach is large have lived for years in a good or moderate state of nutrition, and certainly, except in very severe cases, quite enough food passes through to cause a secondary enlargement of the stomach. But even were the enlarged stomach present before the achalasia arose, a consideration of the mechanics of the part and a study of *x*-ray appearances should dissuade one from proposing that the former is the cause, or at least one of the causes, of the latter, though the oesophageal disease may be aggravated by the gastric enlargement once the disease is advanced.

With regard to Dr. Jordan's second factor—namely, toxaemia produced by intestinal stasis—it is unfortunate that he is not more exact in his description of this presumably important factor. Without more than mentioning the fact that intestinal stasis is not a constant, even if it be a frequent, complication, I should like to ask Dr. Jordan, (1) What does he suppose is the nature of the toxaemia? (2) Exactly what tissues does he mean by those concerned? and (3) What is the precise nature of the lesion entailed? We have surely arrived at a time when statements of the presence and action of intestinal toxaemia should be abandoned unless we have concrete evidence of their existence and activity. The process of explaining one unknown by means of another unknown is time-worn, but not time-honoured.

Finally, we find that Dr. Jordan summons to his aid an idiosyncrasy of the individual which he (Dr. Jordan) is unable to explain. I have already pointed out that it is a method only too well recognized to explain one unknown by having recourse to another. While I am the last to deny that differences in the individual do exist, and are important in certain specific instances, yet I am persuaded that the terms "idiosyncrasy" and "diathesis" have become convenient bolt-holes into which one can retire when the problem becomes too difficult to solve. Under such circumstances, the whole question of individual variation in relation to disease is placed in an invidious position, and is eyed askance by more sober and painstaking investigators.

In conclusion, may I say that with one of Dr. Jordan's statements I find myself in almost complete agreement—namely, that "the exact pathology of the disorder is still open to argument." I have always maintained that although a lesion of Auerbach's plexus has been present in every case of achalasia which I have studied, yet I do not think it probable that this is the only anatomical lesion which may produce the disease. Even were it the one and only lesion, yet, as I have stated frequently, the exact pathology is still in doubt until we have shown to what this lesion is itself due. Surely, however, the question should be considered as open to investigation rather than to argument. The latter method, while serving sometimes to consolidate the steps already made, and to point the way to future ones, can never of itself solve any problem. It is with further investigation, such as is even now in progress, that the exact pathology of achalasia of the cardia will eventually become known.—I am, etc.,

Rockefeller Institute for Medical Research, New York, Oct. 22nd. GEOFFREY W. RAKE.

SPINAL MANIPULATION

SIR,—Dr. T. Marlin, in his interesting article "Some common complaints amenable to spinal treatment," in your issue of October 24th, makes a number of statements that I cannot allow to pass unchallenged. Thus, he states that the benefit derived from spinal manipulation cannot be ascribed to bone-setting or to the breaking down of adhesions, because the force used in manipulation is not sufficient to break down adhesions, and that any sound heard during manipulation is due to separation of the articular surfaces, and not to the replacement of subluxations.

As regards the impossibility of breaking down adhesions, this cannot be correct. While admitting that very powerful adhesions cannot always be removed in the way described, it must be remembered that all adhesions arise by a gradual process from the slow organization of deposits or infiltrations, and that all adhesions are extremely weak at first, and slowly increase in intensity. During the initial stages they should present no difficulty whatever to their being broken down by manipulation, provided always that this is correctly applied. I can assure Dr. Marlin that I have broken down such adhesions in the vertebral column in thousands of cases.

As regards the causes of the articular sounds heard during manipulation I cannot see how they can be induced by mere separation of articular surfaces. If they were,

they would be heard again and again upon successive stretchings at intervals of a few seconds, such as is done when trying to remove tissue tension in the neck previous to manipulation thereof; this is, however, not the case. The sounds heard when force is applied with sufficient intensity to cause such separation are, in my opinion, *not* due to the separation itself, but to the fact that such separation allows of partial or complete reposition of displacements, because it has removed the obstacle to the muscles and ligaments that have been persistently trying (in consequence of their chronic state of overstretching) to effect such adjustment. I must also point out that if one has correctly diagnosed where and in which direction any displacement exists, makes a manipulative movement in the opposite direction, hears an articular sound, and then finds that change of position has resulted whereby the displaced bone has moved towards, or right into, its correct place, one is compelled to conclude that the sound heard was that of a bone moving. The best example of this is to be found in malrotations of the fifth lumbar vertebra on the sacrum, whereby a pelvic tilt is induced. Say that the spine of the vertebra in question is found deviated to the left, and that the posterior left half of the pelvis is higher than the right; after the usual preparation by relaxing movements, if a rotary movement is made of the lumbar region contrary to the one in which the malrotation exists, a loud articular sound is the usual result, and immediately afterwards the spine of the fifth lumbar vertebra is no longer to the left, and the pelvis is now level. This can only be due to an actual movement of reposition of the displacement in question.

Dr. Marlin stresses the point that the original skiagram that apparently showed a displacement can often be accurately reproduced in a second skiagram (after so-called reposition) taken with the patient in another position, and considers this to be evidence against any such reposition having been effected. To my mind it is rather the opposite, but in any case it is worthless as clinical evidence. The main point in comparative skiagrams is that they are to be taken with the same centring and with the patient in exactly the same position each time. I maintain that if, under such identical circumstances, it is found that the bones do not occupy the same positions, and that one cannot reproduce the original skiagram, then some alteration of position in the bones must have taken place.

In conclusion, I would like to emphasize the fact that the laws of pathology and clinical evidence concerning displacements in the extremities are the same as those concerning displacements in the vertebral column, and that the broad lines of treatment for such displacements are identical in both cases.—I am, etc.,

London, W 1, Nov. 5th. EDGAR CYRIAX, M.D.Ed.

INJURIES OF THE KNEE-JOINT

SIR,—Mr. Naughton Dunn's paper in the *British Medical Journal* of October 10th has drawn attention to one among several points of interest. I refer to the comparative freedom from septic infection in operations opening the synovial cavity. In my student days we observed with what caution—almost fear—surgeons operated on the knee-joint. To-day one surgeon alone can refer to a series of 250 operations for damage to cartilages and 34 for loose bodies. The treatment of wounds of this joint has shown a corresponding improvement. In the *Medical Journal of Australia* for September, 1920, I published a review of fifty cases of wound of the knee-joint under the care of my colleagues Major Bearne and Captain Carleton and myself, in a general hospital during the war. All were severe; many of the joints appeared hopelessly shattered; but of the fifty patients only two had to submit to amputation, the remainder being in due course evacuated to England, in nearly every case with strong, useful legs.—I am, etc.,

St. Luke's Hospital, Hebron, Palestine, Oct. 27th. H. W. WEBBER, M.S.Lond.

DOSAGE OF DIPHTHERIA ANTITOXIN

SIR,—In your issue of October 31st, "M.D., D.P.H." has attacked me with the full force of his logical artillery without, I think, inflicting any mortal wound. No one can deny that five days after a large intravenous injection there is still a theoretical excess of antitoxin in the blood, but my contention is that the patent may be helped if this excess is maintained at the highest possible level so long as there is reason to believe that any fresh toxin is being produced. "M.D., D.P.H." states that toxin, on making its way through the superficial tissues, encounters an overwhelming amount of antitoxin ready to neutralize it immediately. This seems to me to be the crux of the matter.

If the antitoxin does in fact immediately combine with *all* the toxin, then, *cadit quaestio*, a single dose is ample in all cases. But I cannot believe that this statement is an adequate description of what happens in the treatment of children suffering from diphtheria. If we grant, for the sake of argument, the questionable assertion that antitoxin does neutralize toxin *immediately*, there is still the affinity of the tissues to be considered. Surely there must always be some partition of toxin between the circulating antitoxin and the cells of the body. Only if the concentration of antitoxin in the blood stream becomes infinite (an absurdity), or if the tissues are highly refractory, will the coefficient of partition approach zero.

One cannot help feeling that the tissues of a young child are relatively more susceptible to the evil effects of diphtheria toxin than are those of a guinea-pig. (By the way, has "M.D., D.P.H." ever seen natural diphtheria, with the formation of a false membrane, in a guinea-pig?)

Unfortunately, in human diphtheria we are conducting our operations in a test tube which will insist on combining with one of the reagents. We must therefore do all that we can to assist the reaction to proceed in the required direction by supplying a large excess of our neutralizing agent. These efforts may be futile, but I am not convinced that they must be.

It is not very easy to accept the Schick test as the sole criterion of immunity in diphtheria without certain reservations. For instance, I myself am so Schick-positive that my arm desquamates for several weeks after an injection. Nevertheless, though I have come into intimate contact with cases of malignant diphtheria during the past five years, and though I have had membrane coughed into my face on numerous occasions, I have not, as yet, contracted the disease. Furthermore, we have at present under observation a Schick-positive boy of 6 who is carrying virulent bacilli in his nose and throat. Conversely, it is possible—*pace* "M.D., D.P.H."—to point to Schick-negative individuals who have contracted a disease clinically indistinguishable from diphtheria. It seems to me that a healthy adult, with no circulating antitoxin whatever, may still be able to mop up (so to speak) a considerable amount of toxin through the intervention of his reticulo-endothelial system. In children this mechanism is not fully developed, hence (among other reasons) their greater susceptibility to the disease.

On the whole, I am still not prepared to admit that in giving repeated doses of antitoxin I am guilty of any lapse from that austerity of mind which is (who could doubt it?) the natural perquisite of those fortunate individuals who are able to work in the cool, chaste atmosphere of the laboratory.—I am, etc.,

Grove Hospital, S.W.17, Nov. 2nd. J. B. ELLISON.

ACUTE SPONTANEOUS HYPOGLYCAEMIA

SIR,—The authors of the paper with this heading, in your issue of November 2nd (p. 837), do me the honour of referring to an article of mine on hypoglycaemia, which appeared in the *British Medical Journal* in 1930,[1] but, curiously enough, they do not mention an earlier article, published in 1924,[2] the same year as Harris's paper, nor another which appeared in 1927.[3] The former is, as far as I can discover, the first where the pathology and etiology of hypoglycaemia are discussed in detail and illustrated by different types of case. The authors complain that my 1930 paper is lacking in details, but, as it was concerned with a general survey and classification of 200 cases of chronic hypoglycaemia which had come under my observation, it was not possible to deal with individual examples, and readers were referred to my previous communications on the subject for these. I am aware that my 1924 paper, and the still earlier reference I made to the clinical importance of spontaneous hypoglycaemia in opening the discussion on "Acidosis and alkalosis in children" at the British Medical Association Meeting in 1923,[4] are not mentioned in American bibliographies on hypoglycaemia; but that is not unexpected, as it is common for American and Continental authors to overlook earlier work published elsewhere, and give priority to their own countrymen.—I am, etc.,

London, W.1, Nov. 7th. P. J. CAMMIDGE.

TREATMENT OF ANTHRAX BY N.A.B.

SIR,—In your review of the annual report of the Chief Inspector of Factories in the *Journal* of September 12th reference is made to the serum treatment of anthrax. It does not seem to be known in England that novarsenobenzol is a specific for anthrax infection. I do not know to whom the honour is due of introducing this method of treatment to the medical profession in South Africa, but I think I am right in saying that throughout the Union the N.A.B. treatment is the one generally adopted.

An intravenous injection of 0.6 gram daily or on alternate days, according to the severity of the symptoms, will not only save the life of the patient, but will render surgical intervention unnecessary in the majority of cases. Furthermore, serum is not always readily available to the general practitioner, whereas N.A.B. forms a part of his ordinary armamentarium.—I am, etc.,

Durban, Oct. 14th. A. B. M. THOMSON.

SIR,—The following case (reported by permission of Dr. R. Kelson Ford, medical superintendent of St. Olave's Hospital, Rotherhithe) appears to demonstrate the usefulness of treating anthrax by N.A.B., either alone or in conjunction with serum.

A lighterman, aged 28, was admitted to St. Olave's Hospital on June 8th, 1931, with a history of having four days previously scratched a small pimple on the left side of his face. The pimple increased in size, developed a dark centre almost the size of a shilling, and around it were some vesicles with considerable oedema. He had on admission a severe headache, temperature 101.8° F., pulse rate 96, and respiration rate 20, and was diagnosed in the receiving room as anthrax, a smear from the lesion showing the presence of anthrax bacilli. The following day another smear was taken, and anthrax bacilli found.

It was decided to try the effect of N.A.B., but we did not feel justified at first in treating the patient without Sclavo's serum in addition. Sclavo's serum, however, was *not used* after the initial dose. He was given soon after admission 0.6 gram N.A.B. and 80 c.cm. Sclavo's serum intravenously. This was followed by a slight rigor lasting five minutes. Aspirin 10 grains and phenacetin 10 grains were given for headache. That evening the patient's temperature fell to 98.6°. He vomited once. The next day his condition improved, oedema of face was less, and he was comfortable. The cervical glands were swollen. That evening the patient's temperature was 98.8°, and he was given 0.6 gram N.A.B. intravenously (no Sclavo's serum was used). The following day the patient's temperature was 98.4°, the oedema was still subsiding, pulse and colour were good, but he vomited a little on one occasion. At night his temperature was 97.2°, and he slept well. Next day the temperature rose to 99°, but the general and local conditions were still improving. He was again given 0.6 gram N.A.B., and from this time he made a rapid and uninterrupted recovery. The lesion gradually dried, scabbed, and separated. The patient's Wassermann reaction was negative.

Anthrax is treated, as a rule, with anti-anthrax serum, such as Sclavo's serum or Sobernheim's serum. The results are variable. Sclavo, by the use of large doses of serum over many days, reduced his mortality rate from 24 per cent. to 6 per cent. in a large number of cases. Other observers have a much higher mortality rate. It is now claimed that salvarsan acts as a specific in human anthrax. This treatment was first used by F. Becker. Pijper[1] [2] states that at Pretoria Hospital, South Africa, all cases entering with anthrax were treated exclusively with salvarsan. There were no deaths in records of over forty consecutive cases. The benign course of this case was in marked contradistinction to another case of anthrax admitted to St. Olave's Hospital some months previously, which was treated by Sclavo's serum only, but progressed to a septicaemia and death.—We are, etc.,

Stamford Hill, N.16, Oct. 16th.

VACCINATION AND ECONOMY

SIR,—Like Dr. Floyd, I was an assistant medical officer on the small-pox ships in the 'nineties, an experience which to me (and I have no doubt to him) has been of inestimable advantage in after-life. There was then no suggestion that severe and mild small-pox were separate entities which bred true. Each was recognized as a phase of the same disease, and whether an individual developed a severe or a mild attack was regarded as depending upon the amount of his acquired or natural immunity. That the latter was considerable in some individuals was shown by the fact that mild discrete cases—or, in modern phraseology, "minor" small-pox—occurred in unvaccinated individuals, and even in children, who derived their infection from severe or major cases. On the other hand, confluent cases originated from the mild ones.

Dr. Haldin-Davis suggests the discontinuance of general vaccination on the grounds of economy, but in my opinion economy is not the most important consideration, but whether the present inefficient one-scar operation, as now officially recognized, is worth doing at all. Is it not giving rise to a sense of false security? And is it not likely that, in the event of "major" small-pox again predominating, the protection will prove to be an illusion, the children being the chief victims? If this is so, vaccination will be further discredited in public opinion, and opposition to it will be increased when efficient vaccination becomes again of paramount importance.—I am, etc.,

"WHAT IS LIFE?"

SIR,—I appreciate the patience of Professor Haldane's reply to my letter. The argument in that letter was, summarily, that the conception of wholeness had been accepted much more widely by biologists than Professor Haldane's words would suggest. Was not General Smuts right when, in speaking to the British Association of the mechanistic ideas recently current in physiology and biology, he said, "All that is passing if not already past"? Such a work as that of Dr. E. S. Russell, *The Interpretation and Development of Heredity*, seems to be more representative of current biological thought than Professor Hogben's publication, and the text around which Dr. Russell's book is written is the essential unity of the living organism.

Professor Haldane considers that the conceptions of matter and mechanism which biology took over from physics still require some hard knocks before we can feel assured that they are satisfactorily dead, and it is not for me to question his judgement. On the other hand, the prospects of understanding that have been opened up by the remarkable disappearance of boundary walls between different branches of science make one impatient to see the work of synthesis continue and inclined to leave the few remaining "mechanists" to starve on their desert islands. I may, perhaps, without impertinence express my admiration for Professor Haldane's contributions towards that unification of study of the living organism which seems to promise results of which there was no prospect under the regime of sectional study.—I am, etc.,

Liverpool, Nov. 7th. K. W. MONSARRAT.

TEMPORARY TREATMENT WITHOUT CERTIFICATE

SIR,—The Mental Treatment Act has been in operation since the beginning of the year, and it has now become apparent that Section 5, which deals with the new class of temporary patients, a section from which so much was hoped that it was described in an official publication as an "epoch-making" advance, is little more than a dead letter.

In a communication which appeared in your columns on December 6th, 1930 (p. 979), I pointed out that on account of the ambiguity in the wording of Section 5 its practical application would depend on the view taken by the Board of Control. The Board's interpretation, it now appears, has been framed on the narrowest possible lines—on a literal reading, in fact, of the words "incapable of expressing himself as willing or unwilling to receive treatment."

It is hardly necessary to point out that this interpretation nullifies practically entirely the usefulness of the section. Interpreted in this way it can apply only to a very small number of cases—certainly less than 5 per cent. If that were all we might be able to reconcile ourselves to it as another example of official claudication. Further harm has resulted from the advertisement given to Section 5 in the beginning, and the consequent impression received by doctors and the public of its value as a means of avoiding certification. This impression, in view of the Board's decision, is now seen to be erroneous, but in the meantime the general bias on the subject of the stigma of certification has been intensified. The word "certification," in fact, has become invested with a new and somewhat sinister connotation.

The anomalous situation that has thus arisen renders the task of those who are attempting to treat mental patients within the terms of the Mental Treatment Act and the principal Act, one of exceptional and unnecessary difficulty. Is it not possible, therefore, for the Board of Control to reconsider their attitude in the light of modern therapeutic requirements, and adopt a more liberal interpretation of the section in question?—I am, etc.,

London, W.1, Nov. 9th. FREDERICK DILLON.

SUN-BATHING AND PULMONARY TUBERCULOSIS

SIR,—While the ultra-violet light of the sun has wonderful health-giving properties for many people, there is one notable exception, and that is where tuberculosis of the lungs is present, either diagnosed or unsuspected. A large number of people, without knowing it, suffer in greater or lesser degree from this disease, and in these circumstances uncontrolled use of the sun may do a great deal of harm, and may light up quiescent tuberculosis, thus turning it into an active case with fever, sputum, haemoptysis, loss of weight, and all the usual symptoms. It cannot be too strongly emphasized that care should be exercised when undertaking a course of sun-bathing, or indeed even when contemplating a course of ultra-violet light provided by mechanical means. The promiscuous use of this form of treatment may cause much damage.

Sun treatment is now admitted to be the most satisfactory method of treating cases of localized and surgical tuberculosis—that is, tuberculosis of bones, joints, serous membranes, glands, etc.—but, on the other hand, the treatment of pulmonary tuberculosis by heliotherapy has fallen into disrepute for very good reasons. There are, however, a limited number of cases of pulmonary tuberculosis for which sun and ultra-violet light treatment is beneficial, cases especially which approximate to the surgical or localized type, where there is, for instance, a small localized lesion, perhaps at one of the apices, which, although not in any sense active, refuses absolutely to shut off and heal. Cases of chronic pleurisy with much thickening and adhesions often improve in a remarkable manner under sun treatment. Open sores, fistulae, and unclosed empyemata are also very suitable for this form of therapy.

Sunning should be done as far as possible in an open space, with free circulation of air all round, and not in a confined space; it is the rays of the sun combined with the cooling power of the air (seen in such a marked degree in the Swiss Alps) which confer the benefit. Sun-bathing does not mean getting boiled and uncomfortable. It should be done gradually, the amount of exposure being graduated from day to day; the head and neck should be shaded, and patients should go brown and not red. The time of day to carry out the treatment should be in the early morning during the summer months, and towards the middle of the day during the winter months. Once the patient is pigmented and on the way to recovery, he can stand more and more exposure. If he becomes fatigued, perspires a great deal, or has a febrile reaction, then the time of exposure must be cut down. Dark-haired people become more easily accustomed to the sun's rays than the fair-haired and the red-haired.

What I particularly wish to emphasize in these few remarks is the very real and definite danger of uncontrolled sun-bathing—especially when there is tuberculosis of the lungs, already diagnosed or sometimes not even suspected.—I am, etc.,

BERNARD HUDSON, M.D., M.R.C.P.

Davos Platz, Oct. 30th.

WINTERING ABROAD

SIR,—Under the title "A plea for British spas" a correspondent calls attention (October 17th, p. 726) to "the enormous numbers of the wealthier classes who, partly obeying the dictates of fashion and partly through ignorance and prejudice, have adopted the practice of residing abroad for cures at spas or sanatoriums, or of wintering abroad to escape the so-called rigours of the English climate." He goes on to speak of "the claims and advantages of the Channel Islands, Malta, the British West Indies, South Africa, and even distant New Zealand." I do not question the sincerity of the patriotic zeal which inspires such a line of reasoning, but I venture to think that decisions based largely on patriotism are often unwise and, in the end, may prove disastrous to the individual as well as to the nation.

I spent several days in London last week. The weather, I was told, was fine. Certainly it did not rain, and there was no real fog. But to one with delicate throat or bronchial tubes, or even accustomed to the clearer clime of Southern France, there was a moist, clammy, muggy feeling in the air that bespoke the coming winter. There was little difference in conditions as I passed through Havre and Paris; the sky, perhaps a little clearer, but the valley of the Seine and of the Thames closely resemble each other. I left Paris on October 23rd, and, sixteen hours later, arrived in Cannes in clear sunshine, the thermometer remaining, between 9 a.m. and 3 p.m., close to 20° C., or 68° F. In this morning's paper I read that on the same day in London there was a hoar-frost, and that the thermometer had fallen below freezing point.

Now, Sir, I honestly do not desire to make any claim *pro domo mea*, but I maintain that such conditions spell danger for many individuals, young and old. The inference is obvious that it may be for their own and their country's benefit for many to winter abroad. An Englishman returning home in good health in spring is surely of more value to his country than a sick and ailing or dangerously ill Englishman remaining at home. Every doctor knows—the lengthening obituary column in our morning paper tells the tale—that with the fall of temperature in winter the death rate rises.—I am, etc.,

Cannes, Oct. 25th. A. A. WARDEN, M.D.

*** While not convinced by Dr. Warden's argument, we print his letter because of its topical interest.—ED., *B.M.J.*

Obituary

J. S. C. DOUGLAS, M.A., D.M., M.Sc.,

Dean of the Faculty of Medicine and Joseph Hunter Professor of Pathology, University of Sheffield

As briefly announced in our last issue, Professor J. S. C. Douglas died at Llandudno on October 30th, after a few weeks' illness. His death is a serious loss to the University of Sheffield and its Faculty of Medicine, with which he had been identified since his appointment to the chair of pathology in 1915.

James Sholto Cameron Douglas, elder son of Mr. Claude Douglas, F.R.C.S., consulting surgeon to the Leicester Royal Infirmary and past-president of the Midland Branch of the British Medical Association, was born in 1879, and from Haileybury College went, with an open science exhibition, to Christ Church, Oxford. He graduated B.A. with first-class honours in the final school of natural science in 1902, M.B., Ch.B. in 1905, M.A. in 1908, and M.D. in 1912. On leaving Oxford he entered Guy's Hospital with a university scholarship, and in 1903 was appointed Webb scholar in bacteriology at St. George's Hospital. As Radcliffe travelling Fellow he studied at Copenhagen and Dresden in 1906, and in the following year, after appointment to the Philip Walker research studentship in pathology, he returned to Oxford on his election as Fellow and lecturer in natural science at St. John's College. He was next appointed lecturer in pathology and bacteriology in the University of Birmingham, where he received the M.Sc. degree, and not long afterwards he accepted a corresponding position in the Victoria University of Manchester. During the war he was attached to the 3rd Northern General Hospital, with the rank of Captain R.A.M.C.(T.F.). In 1915 he was elected to the Joseph Hunter chair of pathology in the University of Sheffield, and became honorary pathologist to the Royal Infirmary and the Royal Hospital, Sheffield, also to the Jessop Hospital for Women and the Hospital for Sick Children; in 1921 he accepted the onerous post of dean of the Faculty of Medicine.

On two occasions Douglas was awarded scientific grants by the British Medical Association. At the Annual Meeting in Liverpool in 1912 he was secretary of the Section of Pathology; when the Association met in Glasgow in 1922 he was vice-president of the Section of Pathology, and at Nottingham in 1926 he was president of the Section of Pathology and Bacteriology.

A colleague writes:

During the sixteen years that Douglas was in Sheffield he won the affection and esteem of all who came in contact with him. His ripe experience and wide knowledge of pathology were always freely at the service of all who sought his advice, and he spared no pains to give them of his best. His department, with its various subsidiary laboratories at the hospitals of the city and its connexion with municipal departments, ran smoothly and efficiently under his excellent organization, because all who came in contact with him realized his transparent honesty of purpose and his high standard of conduct. Douglas had no axes to grind, and his word was always his bond.

Latterly he had been obliged to some extent to nurse his strength, and during the last ten years the heavy duties of dean of the Faculty of Medicine, added to those of the chair of pathology, occupied all his time and energy. Both were carried out with that care and thoroughness which characterized everything he did. His unselfish devotion to the University, the quiet dignity of his manner, and his kindly and generous nature will long remain happy memories to all his colleagues.

The death occurred in a nursing home in Liverpool on October 26th of Dr. PIERCE JONES of Portmadoc, at the age of 57. Soon after graduating M.B., Ch.B. of Glasgow University in 1900, he became assistant to the late Dr. W. Jones Morris, whom he succeeded in the appointments of Poor Law medical officer for Portmadoc and Glaslyn districts, and medical officer to the Post Office local staff and the constabulary. He had a large general and panel practice, and was highly esteemed by his patients and by all with whom he came in contact. He took great interest in local affairs, and thirteen years ago headed the poll for election to the urban council, of which he became chairman within four years of his first election. He was for several years chairman of the Health Committee and represented the council on the Carnarvonshire Joint Sanitary Authority. Dr. Pierce Jones was a member of the South Carnarvon and Merioneth Division of the British Medical Association, of which he was chairman in 1925–26, and was vice-chairman and representative of the Division on the Branch Council at the time of his death.

We have to record the death, on October 21st, of Dr. RICHARD JONES of Llandudno, aged 73. After studying medicine at the Universities of Glasgow and Edinburgh, he graduated M.B., C.M.Ed. in 1880, proceeding to the M.D. with honours in 1891, in which year he also obtained the D.P.H.Camb. He began practice at

Blaenau Festiniog as partner with the late Dr. Robert Roberts. He took a prominent part in the public life of Merioneth, having been appointed a justice of the peace, a member of the county council, and medical officer of health for Blaenau Festiniog. He removed to Llandudno in 1920, where he became popular with all sections of the community. He was a member of the North Carnarvon and Anglesey Division of the British Medical Association, and was an ex-president and for many years a member of the council of the North Wales Branch. He was representative of his Division at the Annual Meeting of the Association in Oxford in 1904. Dr. Richard Jones was medical officer of the Lady Forester Home, Llandudno, surgeon to the Sarah Nicol Cottage Hospital, Llandudno, and medical referee under the Workmen's Compensation Act. In 1929–31 he was a member of the Ministry of Health's joint advisory committee on disciplinary procedure.

Dr. F. C. FOSBERY, formerly of Bath, died on October 29th, aged 59. He received his medical education at the Bristol Royal Infirmary and St. Thomas's Hospital, and took the qualifications of the English Conjoint Board in 1894, and the degree of M.D.Brux. in 1899. After holding several house appointments he entered a partnership at Bath in 1900, and continued to practise there until a few months ago, when he retired through ill-health and went to live at Freshford. He was at one time public vaccinator of the Bath urban district, and assisted in the formation of the Bath Ante-natal Clinic, which he conducted until it was merged with the City Health Department. Dr. Fosbery was a member of the Bath Division of the British Medical Association, and was for some years treasurer of the Bath Panel Committee. During the war he was in medical charge of the Belgian refugees and of the Belgian convalescent soldiers in Bath, as well as medical officer of the V.A.D. Hospital at Rock House, Lansdown, and to the local branch of the W.A.A.C.

Dr. ISMAY BANNERMAN, who died on November 2nd, studied medicine at Edinburgh, and after graduating M.B., Ch.B., acted as house-surgeon at the Royal Infirmary. He then assisted his father, Dr. James Bannerman, in country practice at Stanhope in Weardale, where he was greatly liked by all his patients. Recently he joined the R.A.F.M.S., and was undergoing training at Halton Camp preparatory to foreign service. On October 29th he met with a severe motor accident. He was promptly conveyed to the R.A.F. Hospital, and there succumbed four days later, despite the most unremitting efforts of the staff.

The following well-known foreign medical men have recently died: Dr. LORTAT-JACOB, physician to the Hôpital Saint Louis, Paris; Dr. JOHN A. FOOTE, a Washington paediatrist, aged 56, of coronary thrombosis following influenza; Professor S. J. ZLATOGOROFF, a Leningrad bacteriologist, aged 58; Dr. AUGUST FOREL, the eminent Swiss psychiatrist and sociologist, and author of works on alcoholism, hypnotism, the sexual question, and the social world of the ants, aged 83; Dr. PAOLO DE VECCHI of New York, the oldest and most representative Italian practitioner in the United States, aged 84; Dr. DUJARIER, surgeon to the Hôpital Boucicaut, Paris; Dr. JOHN OSBORN POLAK, professor of obstetrics and gynaecology, Long Island College Hospital, aged 61, of heart disease; Lieut.-General ERNEST WIBIN, inspector-general of the Health Service of the Belgian Army; Dr. LOUIS VILAIN, a prominent Brussels surgeon, aged 61; Dr. LEONARD NAPOLEON BOSTON, professor of physical diagnosis in the University of Pennsylvania, aged 60, of erysipelas; CHARLES ALLEN PORTER, emeritus professor of surgery at Harvard University, aged 64, of carcinoma of the stomach; Dr. J. B. SHELMIRE, an eminent Dallas dermatologist, aged 73; and Dr. EUGEN LYMAN FISK, a pioneer in advocating the periodical examination of healthy persons by life insurance societies.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

Pinsent-Darwin Studentship in Mental Pathology

An election to this studentship will be made next month. The studentship is of the annual value of not less than £200, and is tenable for three years. The student must engage in original research into any problem having a bearing on mental defects, diseases, or disorders, but may carry on educational or other work concurrently. Applications for appointment to the studentship should be sent before December 5th to the secretary, Pinsent-Darwin Studentship, Psychological Laboratory, Cambridge. Applicants should state their age and qualifications, and the general nature of the research that they wish to undertake. No testimonials are required, but applicants should give the names of not more than three referees.

At a congregation held on November 7th the following medical degrees were conferred:

M.B., B.Chir.—*R. B. Mayfield, G. H. G. Southwell-Sander*, W. H. Poole.

M.B.—W. J. Wilkin.

B.Chir.—D. Divine.

UNIVERSITY OF LONDON

Lord Irwin, the late Viceroy of India, and Lord Moynihan, President of the Royal College of Surgeons of England, have been nominated for the Chancellorship of the University of London in succession to Earl Beauchamp, who recently resigned. The election will take place on January 19th.

The following have been recognized as teachers of the University in the subjects indicated, and assigned to the Faculty of Medicine: St. Bartholomew's Hospital Medical College, Drs. Geoffrey Bourne and F. G. Chandler (medicine), Mr. F. C. W. Capps (oto-rhino-laryngology); Westminster Hospital Medical School, Mr. Walter H. Coldwell (radiology); London Hospital Medical College, Dr. Kenneth H. Tallerman (diseases of children—paediatrics); Middlesex Hospital Medical School, Mr. Arthur E. W. Idris (anaesthetics); London (R.F.H.) School of Medicine for Women, Miss Geraldine M. Barry (surgery); St. Mary's Hospital Medical School, Dr. Thomas C. Hunt (medicine).

The Ph.D. degree in hygiene in the Faculty of Medicine has been conferred upon Stephen L. Baker (Middlesex Hospital Medical School) for a thesis entitled "A study of the filterable sarcomas of the fowl."

The Vice-Chancellor has appointed the following additional examiners and associate examiners in obstetrics and gynaecology required for the M.B., B.S. examination in November: Examiners: D. W. Roy, J. D. Barris, and F. J. Browne. Associate Examiners: S. Dodd, W. Gilliatt, and F. Cook.

Presentation Day has been fixed for May 12th, 1932.

After the year 1932 Foundation Day will be celebrated on the Thursday preceding the fourth Monday in November.

The Brown Institution Lectures for 1931 on "The future of bacteriological research" will be delivered at the Royal College of Surgeons of England by Mr. F. W. Twort, superintendent of the Brown Institution, on December 2nd, 4th, 7th, 9th, and 11th, at 4 p.m.

Applications for appointment to the chair of medicine, tenable at St. Thomas's Hospital Medical School (salary £2,000 a year), should be received by the Academic Registrar by November 26th.

Applications for the Geoffrey E. Duveen travelling studentship in oto-rhino-laryngology, and for grants for promotion in research in the subject, should be sent on prescribed forms to the Academic Registrar by December 31st, 1931. The studentship, which is of the value of £450, is awarded annually, but its tenure may be extended. Grants may also be made from the trust fund of the benefaction for promotion of research in oto-rhino-laryngology. Full particulars can be obtained on application to the Academic Registrar at the University, South Kensington, S.W.7.

UNIVERSITY OF LIVERPOOL

Mitchell Banks Lecture

By invitation of the Council, Senate, and Faculty of Medicine Sir Robert Jones, Bt., lecturer in orthopaedic surgery in the University, will deliver the William Mitchell Banks Memorial Lecture, 1931, on "The problem of the stiff joint," on Thursday, November 19th, at 4 p.m. The lecture, which will be illustrated by lantern slides, will be given in the surgical theatre, the Medical School, and is open only to members of the medical profession.

UNIVERSITY OF GLASGOW

A graduation ceremony was held on November 7th, when Principal R. S. Rait presided and conferred the degrees. The honorary degree of Doctor of Laws was conferred on Dr. John Glaister, formerly professor of forensic medicine in the University.

The degree of M.D. was conferred on S. R. Leighton.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

A quarterly meeting of the College was held on November 3rd, when the President, Sir Norman Walker, was in the chair. Dr. T. D. Inch, O.B.E., M.C. (Gorebridge) and Dr. E. R. C. Walker (Aberdeen) were introduced, and took their seats as Fellows. Dr. J. D. A. Gray (Liverpool), Dr. J. G. McCrie (Edinburgh), and Dr. D. N. Nicholson (Edinburgh) were elected Fellows.

The Hill Pattison-Struthers Bursary in anatomy and physiology was awarded to Norman Macdonald, and the Wood Bursary to Alastair W. Wright.

A certificate of qualification to lecture was conferred upon Dr. Donald Stewart.

At an extraordinary meeting, held immediately after the quarterly meeting, it was decided to offer the Honorary Fellowship of the College to John Wheeler Dowden, President of the Royal College of Surgeons of Edinburgh.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At the annual meeting of the Royal Faculty of Physicians and Surgeons of Glasgow the following office-bearers were elected for the ensuing year: President, Mr. R. Barclay Ness; Visitor, Dr. J. M. Munro Kerr; Honorary Treasurer, Mr. J. H. MacDonald; Honorary Librarian, Dr. E. H. L. Oliphant; Representative to the General Medical Council, Mr. G. H. Edington.

In demitting office the retiring president, Dr. John F. Fergus, gave a handsome donation to the Benevolent Fund of Faculty. He also took the opportunity of presenting to the Faculty a silver inkstand, a replica of that in the House of Commons. The stand has engraved upon it the arms of the Faculty and, on the obverse of the lid, an inscription "To the Faculty, Beloved and held in honour by Andrew Fergus, President, 1874-77 & 1883-1886, A. Freeland Fergus, President, 1918-1921, John F. Fergus, President, 1929-1931, from J. F. F. 1931."

Medico-Legal

CHARGE OF MANSLAUGHTER BY NEGLECT: ACQUITTAL OF MEDICAL MAN

At the Manx Sessions at Douglas, before Deemster Farrant and a jury, on October 30th and 31st and November 2nd, Dr. William John Dearden of Ramsey was tried on a charge of manslaughter by neglect of a patient, the wife of a labourer, who died during childbirth. The jury returned a verdict of "Not guilty." The case arose out of inquest proceedings.

The Crown prosecution alleged that Dr. Dearden had caused the woman's death owing to his neglect during her confinement, as, after visiting her when a difficult labour was beginning, he did not return, although sent for on several occasions. The woman was in labour for forty-four hours before her death. On the medical testimony brought forward by the prosecution it was shown that, when further medical help was called in, a shoulder presentation was discovered, and normal delivery could not take place. The Manx Attorney-General quoted authorities to show that, if left unassisted, an impacted shoulder meant very grave risk to the mother. He said that if a person of special knowledge, such as a doctor, did not take the ordinary precautions that should be taken, with the result that the person died, he must meet the consequences of the law. It was possible to be as criminal by doing nothing as by levelling a revolver at a person's head. Dr. Dearden had the responsibility of the normal duty expected of a doctor, and did nothing.

For the defence it was argued that Dr. Dearden did all that he could have done. He had visited the case on the day of the confinement, and had found everything progressing normally, though slowly. There was not the slightest evidence for an insinuation on the part of one of the witnesses—the mother of the deceased, herself a nurse—that he was not sober; he had had only one small whisky on the day in question. On that day he had attended several other urgent cases, and his movements were fully on record. He was awaiting a further summons to the case, but none came. On the following morning he was informed by a relative of the woman that two other doctors were in attendance, and so he concluded that his help was no longer needed. There was no evidence of malpresentation at the time he saw the patient.

Dr. Dearden, in evidence, said that he was engaged in April last to attend the confinement. On June 19th he was called to the patient in the early morning, when he found no sign of labour pains. He stayed at the house for an hour and a half, and returned later, and again stayed, by which time there were still no pains that could be called labour pains, and so he went on his round of visits, confident that everything was going on well. He returned later in the afternoon, and found no change in the patient's condition; she had not reached the second stage of labour, and the presentation was still normal. On arriving home late at night from a professional visit he again went to the house, but finding everything shut up and the lights lowered, and receiving no answer to his slight knock, he concluded that all was quiet, and went away. Neither he nor his family heard any bell that night. He was unable to understand how what was a normal presentation on the previous afternoon could have become a shoulder presentation early the next morning, though if the child was dead, as was the case, he thought there was more likelihood of such a change. He admitted in cross-examination that when asked to take on the case he was told that a previous confinement had been very difficult, and that the woman had been warned not to have any more children but he did not think it necessary to make an ante-natal examination; however desirable that might be, it was not done on the island. He had attended the patient some time previously for heart trouble, and had prescribed for her in the street; she was a very bad heart case.

After Dr. Dearden's evidence had concluded, although the defence announced that it had further evidence as to his sobriety and as to his movements on the critical day, the jury announced that they were satisfied on those points, so that no further evidence was necessary. Further medical evidence was also available on behalf of the defendant, but this was not tendered, and the case for the defence closed.

After concluding speeches, the Deemster, in summing up, quoted the opinion expressed by Lord Chief Justice Hewart in the Court of Criminal Appeal in 1925 (*Rex v. Bateman, British Medical Journal*, 1925, i, 1022), that no matter how many acts of negligence the jury might think a doctor had committed, the negligence must be of such a character as to be gross, or to show such disregard for the life and safety of others as to amount to a crime against the State. As to whether there was shoulder presentation in the afternoon, at the time Dr. Dearden last saw the deceased, no one could say except the mother, who had stated that she had made an examination then and had found a shoulder presentation, but that had not been stated in the previous proceedings. The defendant had to be judged, not by the elevated standard of a specialist, but by that of an ordinary skilled practitioner. If there was a shoulder presentation and the doctor went away without doing anything and did not come back, then there was a case of gross negligence, but if the doctor had come to the conclusion even though erroneously, that the woman was suffering from uterine inertia, and not malpresentation, then the evidence of negligence must be regarded as very remote. The difficult point the jury had to consider was whether it was necessary for the doctor at his last visit to have made a further examination so that the malpresentation might have been discovered. If there was any doubt about their conclusion they should give the defendant the benefit.

The jury, after an absence of half an hour, returned a verdict of "Not guilty." The Deemster, addressing Dr. Dearden, said: After a long and careful trial you have been discharged by a jury of your fellow countrymen. They have found you "Not guilty," and I have pleasure in congratulating you on the verdict.

Medical Notes in Parliament

[From our Parliamentary Correspondent]

The King opened the new Parliament on November 10th. No health legislation was forecast in the Speech from the Throne. Joining in the debate on the Address in the House of Commons on the same day, Mr. Lansbury, as Leader of the Opposition, remarked that the Prolongation of Insurance Act would lapse at the end of 1931, and that if nothing were done many unemployed persons would lapse from National Health Insurance as well as forfeit pensions rights. He asked the Government to state its intention in the matter.

Mr. MacDonald said he hoped this part of the session would be short. The Expiring Laws Continuance Bill would have to be dealt with, and the question of the prolongation of insurance had not been overlooked. The Minister of Health had the matter in hand, and if a question was asked at the end of this week or the beginning of next week the House would be informed what the Government proposed to do.

The Parliamentary Medical Committee will be reconstituted at an early date.

Appointments announced on November 11th included that of Dr. Walter Elliot as Financial Secretary of the Treasury, a post he held before the General Election, and of Mr. Ernest Brown as Parliamentary Secretary to the Ministry of Health.

The Services

DEATHS IN THE SERVICES

Colonel Frederick James Greig, C.M.G., late R.A.M.C., died at Seaford, Sussex, on October 6th, aged 68. He was born in London on February 3rd, 1863, and was educated in the Medical School of the Royal College of Surgeons, Ireland, taking the L.R.C.S.I. in 1884 and the L.R.C.P.Ed. in 1885. Entering the Army as surgeon on August 1st, 1885, he became lieutenant-colonel after twenty years' service, and retired on August 26th, 1905. After retirement he was employed at Stirling, where he became senior surgeon of Stirling Royal Infirmary and honorary consulting surgeon to the Royal Victoria School, Dunblane, and also a J.P. for Stirling County. He served on the North-West Frontier of India in the Hazara campaign of 1891 (medal with clasp); in the Miranzai campaign of 1891 (clasp); and in the South African war in 1899-1900, when he took part in the relief of Kimberley, and in operations in Orange River Colony, including the actions at Paardeberg, Poplar Grove, and Driefontein, receiving the Queen's medal with three clasps. He rejoined for service in the war of 1914-18 on August 31st, 1914, was promoted to colonel on July 4th, 1915, and served as A.D.M.S. of the 36th Ulster Division, being mentioned in dispatches in the *London Gazette* of January 4th and May 29th, 1917, and receiving the C.M.G. in 1917. After the war he was employed as superintendent of the Ministry of Pensions Hospital at Newcastle-upon-Tyne. He married Isabella, daughter of the late James K. Morton, and leaves a widow and one daughter.

Colonel Frederick James Morgan, C.M.G., C.B.E., late R.A.M.C., died at Putney on September 30th, aged 69. He was born in London on June 21st, 1862, was educated at Westminster Hospital, and took the M.R.C.S. and L.R.C.P. Lond. in 1886. Entering the Army as surgeon on February 5th, 1887, when he passed first into Netley, he became lieutenant-colonel on May 12th, 1911, and colonel in the long war promotion list of March 1st, 1915, retiring on June 21st, 1919. He served in the South African war, 1900-2, when he took part in operations in Cape Colony; in the Orange Free State, including the actions at Paardeberg, Poplar Grove, Karee Siding, Vet River, and Zand River; and in the Transvaal, including actions at Johannesburg and Pretoria; was mentioned in dispatches in the *London Gazette* of April 16th, 1901, and received the Queen's medal with three clasps and the King's medal with two clasps. In the war of 1914-18 he served as an A.D.M.S., and subsequently as D.D.M.S., was mentioned in dispatches in the *London Gazette* of June 15th, 1916, January 4th, 1917, and May 25th, 1918, and received the C.M.G.

Medical News

The annual dinner of the Yorkshire Aberdeen Graduates' Association will be held at the Midland Hotel, Bradford, on Friday, November 20th. Lieut.-Colonel David Rorie, D.S.O., will be the chief guest. The honorary secretary, Dr. J. G. Thomson, 33, Vernon Road, Leeds, will be pleased to supply further information.

The eighty-sixth half-yearly dinner of the Aberdeen University Club, London, will be held at the Trocadero Restaurant at 7 for 7.30 p.m., on Thursday, November 26th, under the chairmanship of Mr. D. M. Cowan, M.A. (M.P. for the Scottish Universities). The secretary's address is 9, Addison Gardens, W.14.

Mr. H. Morriston Davies, F.R.C.S., will give a lecture on "Surgery in pulmonary tuberculosis" (with kodascope demonstration) at the next meeting of the North-Western Tuberculosis Society, to be held on Thursday, November 26th, in the anatomy theatre, Manchester Medical School. Medical practitioners are cordially invited to attend.

The tenth annual Benjamin Ward Richardson Memorial Lecture, before the Model Abattoir Society, will be given on Wednesday, November 25th, at 5 p.m., at 90, Buckingham Palace Road, S.W., by Mr. Hal Williams. The subject is "Disease and the public abattoir." Admission free, without tickets.

The next quarterly meeting of the Royal Medico-Psychological Association will be held on Tuesday, November 24th, at B.M.A. House, Tavistock Square, under the presidency of Dr. R. R. Leeper. The Maudsley Lecture by Sir Hubert Bond, entitled "Testimonied in his own Bringingsforth," will be delivered in the Great Hall at 3 p.m.

At a meeting of the British Institute of Radiology to be held at 32, Welbeck Street, W., on Thursday, November 19th, at 8.30 p.m., papers will be read by Dr. Ffrangcon Roberts on "Some criticisms of the international protection recommendations," and Dr. G. E. Vilvandre on "The radiology of gall-stones and the gall-bladder." On the following day, at 5.30 p.m., the use of the gastroscope will be demonstrated by Drs. David Levi and Courtney Gage.

At the next meeting of the Royal Microscopical Society, to be held on Wednesday, November 18th, at 5.30 p.m., in B.M.A. House, Tavistock Square, the following papers will be read and discussed: Mr. Conrad Beck, "The substage diaphragm and its functions"; Dr. A. A. Tarkhan, "The effects of fixatives and other reagents on cell-size and tissue-bulk."

As already announced, the annual meeting of Fellows and Members of the Royal College of Surgeons of England will be held at the College in Lincoln's Inn Fields on November 19th, at 3 p.m. A resolution suggesting the representation of Members on the College Council will be moved by Sir Ernest Graham-Little, M.P.

At a sessional meeting of the Royal Sanitary Institute, to be held at the Town Hall, Sheffield, on Friday, November 27th, Dr. H. J. Egerton Hutchins Williams will open a discussion on cerebro-spinal fever at 2.45 p.m.; and at 5.30 there will be a discussion on regional smoke abatement. On the morning of November 28th members will pay a visit to the Sheffield sewage disposal works.

The next monthly clinical meeting for medical practitioners will be given at the Hospital for Epilepsy and Paralysis, Maida Vale, W.9, on Thursday, November 26th, at 3 p.m., when Dr. W. G. Wyllie will demonstrate diplegia in childhood. Tea will be provided; it will be a convenience if those intending to be present will send a card to the secretary.

The Central Council for Health Education will hold its fourth annual conference in the lecture theatre of the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Thursday, November 19th, from 11 a.m.

The Fellowship of Medicine and Post-Graduate Medical Association announces a whole-day course in diseases of the chest, from November 16th to 28th, at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park (fee £2 2s.). An afternoon course in venereal diseases will be held at the London Lock Hospital from November 16th to December 12th (fee £2 2s.). A whole-day course in proctology will be held at St. Mark's Hospital, City Road, from November 23rd to 28th (fee £3 3s.). Two courses will be held from November 30th to December 12th: in diseases of infants, at the Infants Hospital, Vincent Square, daily at 2 p.m. (fee £3 3s.); and in dermatology, at the Blackfriars Skin Hospital, every afternoon (fee £1 1s.). Free lectures will be given on Wednesdays at 4 p.m., at the Medical Society of London, 11, Chandos Street, Cavendish Square, as follows: November 18th, Dr. Isaac Jones on "Glycosuria"; November 25th, Sir Henry Gauvain, "Bone and joint tuberculosis"; December 2nd, Mr. Tudor Edwards, "Surgical chest diseases"; December 9th, Mr. Cecil Joll, "*Goitre, with special reference to thyrotoxicosis.*" Lectures for the M.R.C.P. examination will be given at the same place at 8.30 p.m. as follows: November 16th, Dr. Roodhouse Gloyne, "Clinical pathology of tuberculosis"; November 18th and 23rd, Dr. W. J. Adie, "Diseases of the nervous system," and at 10, Bedford Square, November 25th and 27th, Dr. Knyvett Gordon on "Anaemia" and "Leukaemia." Fee 10s. 6d. per lecture, payable at the lecture room. Copies of syllabuses of all courses, lectures, and demonstrations may be obtained from the Fellowship of Medicine, 1, Wimpole Street, W.1.

According to a ministerial decree of October 22nd the following Italian universities have been chosen for conferring medical degrees: Bari, Cagliari, Catania, Milan, Modena, Naples, Perugia, Rome, Sienna, and Turin.

The October issue of the *American Journal of Surgery* is dedicated to Dr. Rudolf Matas of New Orleans, emeritus professor of surgery at Tulane University, on the occasion of his 71st birthday, and contains twenty-one essays by surgeons in the United States, Strasbourg, Rome, Paris, Barcelona, and Edinburgh.

The list of medical mayors elected on November 9th includes Alderman R. F. Bury (Leamington), re-elected; Dr. W. E. Llewellyn Davies (Llanidloes); Dr. T. R. Griffiths (Kidwelly); Dr. P. H. Seal (South Molton); Dr. J. W. A. Wilson (Wisbech).

After inviting applications from the medical staff of institutions under the London County Council's control, the Mental Hospitals Committee recommends the promotion of Dr. W. D. Nicol, at present deputy medical superintendent, to the medical superintendency of the Horton Mental Hospital, rendered vacant by the recent death of Dr. J. R. Lord.

The statistics of the notifiable diseases for the year 1929 in the various countries and large towns throughout the world have recently been published by the Health Section of the League of Nations. The tables are published, as in the previous two years, without accompanying text, as this is supplied in the monthly epidemiological reports issued by the League. It is noted that though the accuracy of notification is not the same in all countries, notification has recently improved in many.

The institute for the study and treatment of affections of the heart, erected at Bad Nauheim with a donation of 4,700,000 marks by Mrs. Louise E. Kerckhoff of Los Angeles, in memory of her late husband, was dedicated on October 17th. A "Kerckhoff Memorial Fund" of 2,000,000 marks has been provided, the interest of which is to be used for the granting of stipends for scientific research and education. The first of these stipends will be allocated in October, 1932.

Munich exceeded all other German towns in its consumption of milk in 1930; the daily consumption per head was 0.35 litre, as compared with 0.27 litre consumed by Berlin in 1928.

A new school for hygiene and public health is to be erected by the Rockefeller Foundation at Tokio.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are MUSEUM 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Articulate Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Medicava Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick street, Dublin (telegrams *Bacillus Dublin*; telephone 62350 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Naevus

"INQUIRER" writes: Would anyone with special knowledge answer the following queries about a V-shaped naevus on the forehead of a baby a few days old? It was present at birth, is only very slightly raised, and empties on pressure. (1) Prognosis? (2) Treatment recommended to produce least disfigurement? (3) When is correct time for treatment, and will any ill result from delay?

The First Child Welfare Consultation

Dr. J. C. G. DICKINSON (Braunton) writes: Perhaps one of your readers could give the reference to the date of the first child welfare consultation and the name of the patient; it was quoted recently in one of the medical journals, but I cannot now find it.

Anal Neuralgia

Dr. M. E. LYNCH (Newington Green) writes: If "Neuralgia" (November 7th, p. 877) will treat his patients as suggested by Colonel W. P. Macarthur in the *British Medical Journal* of August 22nd last, I am confident that he will find, as my patient has, that the "anal neuralgia" will go. My patient had suffered for years, for his sins, as he thought, and became resigned. The hot-water bottle gave relief. He got no better, but was satisfied when he was not getting worse. A pain so great suggested prostatic trouble, coccygeal trouble, perhaps it was cancer! But since using the saline injections for pruritus he has not had an attack of "anal neuralgia." When a husband and wife suffer similar pains, one is more than hopeful that the *Enterobius* may well be at the bottom of it, for the remedy is simple and to hand.

"SPASM" writes: The query of "Neuralgia" in your issue of November 7th interests me, as both my wife and myself, and my ten-year-old daughter, suffer from what he describes as "anal neuralgia," which occasionally awakens us in the night, but more usually comes on after defaecation. In my own case the pain appears to be localized at and at the level of the prostate, and gives the sensation of an intense cramp-like spasm of that organ, or possibly of one or other levator ani. It starts as a dull ache rapidly increasing to an almost intolerable pain in the rectum. After a few remissions and exacerbations, with possibly a feeling of moving from one side of the rectum to the other, it will die away. At its worst it is quite as intense as biliary colic, a sensation I know only too well. I have found heat good, but I think a small self-administered enema of very cold water stops the pain sooner than anything, especially if it is followed by absolute stillness in the recumbent position. I have searched the literature without avail for some mention of this complaint, and I have only had two patients complain of what I take to be the same thing. I do not think it is neuralgia, because it seldom lasts more

than half an hour, and if it were not that it seems to occur also in the female I would, from my own sensations, ascribe it to some sort of spasm in the prostate.

"C. G. E." writes: Both my father and myself have suffered from this complaint for many years. It occurs in nocturnal attacks, as in the cases quoted by "Neuralgia." I have always found immediate relief is given by the rectal injection of two drachms of glycerin. This is retained for a few moments and then evacuated. The injection is made by means of a small glass syringe.

? Cervical Adenomata

Dr. ARTHUR GREENE (Norwich) writes: With reference to "Cutis Vera's" question (October 31st, p. 831) I would suggest that possibly his patient is suffering from von Recklinghausen's disease.

Alopecia Areata

Dr. R. M. RUSSELL (Ash Vale, Surrey) writes in answer to "Area" (October 31st, p. 831), who inquired about the treatment of alopecia areata: A young man came to me with this trouble. He had small bare patches the size of a shilling, and I gave him the following to paint the patches with every day or two: acid. lact. ʒi or ʒii, ol. ricini ʒii, sp. vini ad ʒiv. In three months the hair grew, fair at first, and afterwards getting dark (he was dark). As his hair had been coming out all over the head this was treated with the follow fluid: thymol 40 grains, sp. vini rect. ʒii, The whole treatment was a complete success.

Income Tax

Change in Nature of Work

"Alpha" was employed as an indoor assistant up to July 31st, 1931. He then commenced practice on his own account, but the venture was a failure, and he has been doing locumtenent work in recent months. How should his liability for 1931-32 be calculated?

*** The definite break in his "employment" justifies—indeed requires—the previous year's basis to be discarded for 1931-32, and he is liable for that year on the amount of his earnings for the year to April 5th, 1932. He can set off his loss while in general practice under Section 34 of the Income Tax Act, 1918, but in calculating the amount of that loss he cannot deduct the capital outlay incurred in starting his temporary practice.

Assistant Receiving Maintenance

"B," an assistant, receives a salary of £500 plus maintenance. Is he liable on an amount estimated to include the value of the maintenance?

*** No, if the terms of the agreement for employment are as stated. But if the agreement were to provide, for instance, that "B" should receive £750 less a deduction of £250 so long as he was in receipt of "maintenance," then he would be liable on the £750.

Use of Car: Appointment

"H" is employed at a military hospital. To get to his work, a distance of four miles, he has to use a car. Can he claim any allowance for this expense?

*** The decided cases lay down the general rule that, while the travelling expenses incurred in carrying out the duties of an appointment are allowable, the expense of travelling from the place of residence to the place where the duties are performed is *not* allowable. [N.B.—This does not apply to profits of general practice assessable under Schedule D]

Obsolescence Allowance and Wear and Tear

"EQUITY" sold his practice as from January 31st, 1931, and is accordingly liable to a revision of the assessments for the year to April 5th, 1930, and the ten months to January 31st, 1931, to the actual profits of those periods. His accounts have usually been made up to July 31st. It has been agreed with the inspector of taxes that for the purpose of the revision of the assessments the earnings will be calculated from fresh accounts prepared for the actual periods. He replaced his car on March 29th, 1928, the obsolescence allowance being agreed at £57. What allowance does he now receive under that head, and how should the wear-and-tear allowance for 1930-31 be calculated?

*** Obsolescence allowances have to be treated as expenses of the year for which the taxpayer's account is prepared. As March 29th, 1928, is outside both the revision accounts "Equity" has no legal claim to that allowance. The wear-and-tear allowance, on the other hand, is in respect of the estimated loss by reason of wear and tear during the year of assessment. In 1930-31 the car was in use for ten months only, and, therefore, "Equity" is entitled only to ten-twelfths of what would be the proper allowance for twelve months.

Income of a Minor

"T. C." has a son to whom a sum of £250 was left when he was 4 years old. The original legacy and the accumulated interest are now represented by a holding of £300 4 per cent. Funding Loan—apparently standing in "T. C.'s" name as natural guardian. The inspector of taxes proposes to treat the interest as income of "T. C" unless evidence of the existence of a trust in favour of the son can be produced.

*** The appropriate evidence would be the probate of the will of the testator who bequeathed the £250 capital to the son. A copy of the relevant clause would show that that amount and the accumulated interest are in the *beneficial* ownership of the minor, and, therefore, that the investment, which is in the legal ownership of "T. C.," must be held by him, not for his own benefit, but as trustee for his son If "T. C." cannot obtain a copy of the clause—for example, by examining the original will at Somerset House—possibly he may still have some letters, etc., from the executors which the inspector can accept as evidence of the bequest.

LETTERS, NOTE

of the Royal Medico- be held on Tuesday, ouse, Tavistock Square, Leeper. The Maudsley cussion in the last two issues of th titled "Testimonied in on early circumcision, I heard to-d delivered in the Great cates and practises the circumcisio between the time of the delivery expression of the placenta. Surely ute of Radiology to be in the early performance of this ope Thursday, November ead by Dr. Ffrangcon

Dr. E. SUTHERLAND RAWLINGS writes the international pro- letter published last week under this G. E. Vilvandre on to be an error—namely, "Penile c he gall-bladder." On frequently in the circumcised than in se of the gastroscope This should have read vice versa: "Pe more frequently in the *non-circumcised* Levi and Courtney *cised*." I should be glad if you would which is of my own construction.

Measles in London

The secretary of the London Fever Hospital, Islington, N.1, writes: In view of the approach of an anticipated epidemic of measles it may perhaps be of interest to your readers to know that this hospital admits patients suffering from this disease, and that some 2,000 such cases have received treatment here during the past ten years.

Corrigenda

In our report published last week (p. 850) of Mr. Philip Hawe's paper on carcinoma of the breast, read before the Liverpool Medical Institution, the sentence commencing "Of 38 early cases" should read as follows: "Of 38 early cases, *excluding* 9 cases not traced, 29 patients were alive five to ten years after operation; of 74 late cases, *excluding* 10 cases not traced, 24 patients were alive five to ten years after operation."

In the *Epitome* for October 17th (para. 347) the dose of acetylcholine was erroneously given as 10 grams to 1 gram daily; it should have been 10 cg. to 1 gram daily. We are informed that Dr. Dainow recommends 10 to 20 cg. daily in spasms of the retinal or cerebral vessels; 40 cg. in arterial affections of the extremities; 1 gram in lead colics; 20 cg. in scleroderma; 10 cg. in varicose ulcer if the patient is confined to bed; and 20 cg. three or four times a week in ambulant cases of varicose ulcer.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 48, 49, 50, 51, 54, and 55 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52 and 53.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 275.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

438 Enteric Fever in the Inoculated

J GADRAT (*Progrès Méd*, September 5th, 1931, p 1556), who records an illustrative case, states that the occurrence of enteric fever in the inoculated depends on three factors—namely, the environment, the date of inoculation, and the method by which it is performed. In the class of typhoid patients usually met with in hospital the number of those previously inoculated ranged from one-eighth to one-eleventh of the total. In the army, on the other hand, enteric fever in the inoculated is rare, except in war time, when fatigue and the consumption of contaminated water favour the opportunities of infection As regards the date of inoculation, the disease is liable to be contracted under two conditions: firstly, when the inoculation has been performed only a short time before, and secondly, when the interval has been too long. Lastly, the disease is much more likely to occur after ingestion than after subcutaneous injection of the vaccine. In the immense majority of cases enteric fever in the inoculated is attenuated, of short duration, and of good prognosis. Its occurrence can be explained by the non-development of an allergic state, and not by the failure of preventive inoculation. It is therefore advisable to test for the presence of an allergic state by the intradermal inoculation of typhoidin, which is a glycerinated filtrate of a typhoid culture; a positive reaction indicates that immunization had taken place. In cases in which the reaction is negative the inoculation should be continued until a positive result is obtained.

439 Amoebic Dysentery Carriers

R GRASSO (*Il Policlinico, Sez Prat*, September 28th, 1931, p 1425) examined the faeces of 60 patients in the medical clinic at Catania who were suffering from various diseases, mostly of a non alimentary character, and found including *amoeba histolytica* in 21 cases, or 35 per cent In the majority of cases (17) the vegetative forms only were found, and only four showed the cystic forms of the organism None of the amoeba carriers had ever suffered from any marked degree of intestinal disturbance Of the 21 patients, 15 had various affections of the respiratory tract, and ten of the latter were suffering from acute or chronic pulmonary suppuration Grasso also made collateral investigations among the families of three patients, and on examination of ten persons found that six were carriers of *Entamoeba histolytica*

440 Decompensated Portal Cirrhosis

Presenting an analysis of 112 cases of portal cirrhosis, in all of which ascites was present, and which were studied at the Mayo Clinic, C B CHAPMAN, A M SNELL, and L G. ROWNTREE (*Journ Amer Med Assoc*, July 25th, 1931, p 237) discuss this condition from various standpoints Snell deals with its clinical features, and gives in tabulated form the etiological factors, symptoms, and physical signs. Alcoholism was found to be the most common cause, and it was noted that practically all the known causes were preventable Ascites was the most prominent symptom, and there was definite evidence of decompensated portal circulation Gastro intestinal disturbances were marked, and abdominal pain and discomfort were frequent. The development of a collateral circulation was a most striking sign, especially in long-standing cases. The diagnosis is usually easy, but if it is doubtful, tests of the hepatic function with bromsulphalein are of value; the reactions are usually positive in portal cirrhosis with ascites The treatment outlined by Rowntree, Keith, and Barner (mercurial diuretics, ammonium salts, and a special diet) was given to 84 patients, 80 per cent. of whom showed some response Chapman points out that, though 84 of the 112 patients died within 16 months of the onset of ascites, the average duration of life of these, and of those still surviving, is longer than has been previously reported, and that the prognosis is more hopeful than is usually considered. From an analogy with compensated and decompensated cardiac disease and nephritis Rowntree believes that the treatment of portal cirrhosis should be instituted early, and be directed to the prevention of decompensation. His own method of treatment, and such surgical measures as omentopexy and the Eck fistula, are briefly discussed He adds that, if decompensation has occurred, the methods of treatment here suggested are the best possible

441 Toxaemia due to Spider Bite

J B BAYS (*Journ Med Assoc of South Africa*, August 22nd, 1931, p. 529) records a personal account of the results of a spider bite In his usual health he suddenly was attacked by complete anorexia and nausea, followed by a restless night and slight fever Next morning he noticed a small yellow mark with surrounding erythema on the dorsum of his right foot, this had been caused by the bite of a spider The redness and swelling, accompanied by considerable pain, rapidly spread up the calf of the leg to the knee, lymphangitis over the front of the thigh and swelling and tenderness of the femoral and inguinal glands ensued, accompanied by considerable constitutional disturbance. Numerous small bullae containing a pure culture of streptococci appeared on the calf; on the fifth day a profuse perspiration heralded a fall in temperature, and improvement in the general symptoms. Desquamation followed, and some swelling and tenderness were still present a month later Treatment consisted of the injection of manganese butyrate, with glycerin and ichthyol applications, and the administration of as much liquid as possible by the mouth

442 Acute Pulmonary Oedema in Measles

P. NOBÉCOURT and J LEREBOULLET (*Arch. de Méd. des Enf*, August, 1931, p 461), who record four illustrative cases in children aged from 4 to 7 years, one of which was fatal, states that pulmonary oedema—an unusual complication—most frequently appears at the height of the attack of measles The onset is always sudden, being characterized by intense dyspnoea, rapid respiration and pulse, increased resonance of the chest due to acute emphysema, weak breath sounds, and numerous fine subcrepitant rales. Under appropriate treatment recovery ensues, but may be delayed by the occurrence of otitis or broncho-pneumonia. Treatment consists in venesection or wet-cupping of the thorax and lumber region, hydrotherapy, the administration of cardiac tonics (of which ouabain in intravenous injections 1/8 or 1/4 mg for five or six days is best), and continuous inhalations of oxygen.

443 Prophylaxis against Rickets

A. G. DE SANCTIS and J. D CRAIG (*New York State Journ of Med*, September 15th, 1931, p 1133), in a preliminary report from the paediatric department of the New York post-graduate medical school and hospital, record that five groups of children were observed over a period soon after birth till the end of the first year of life All were given anti-rachitic treatment as follows Group 1 received three teaspoonfuls of a good brand of cod liver oil daily, Groups 2, 3, and 4 had ten drops daily of irradiated ergosterol, with vitamin D content of 100, 250, and 500 units respectively, while the children in Group 5 were given three tablets daily of a cod liver oil concentrate, approximately equivalent, in rat units, to the dosage in Group 1 The children were carefully watched for signs of rickets; cases showing doubtful signs, or "congenital beading" of the ribs, were excluded from the series. The principal

signs looked for were beading, craniotabes, grooving, and epiphyseal enlargement. It is stated that the dietary conditions, though varied in the whole number, may be considered as being similar in the various groups. It was found that in Group 1, 97 per cent. of children were completely protected from rickets; the other groups, in order, showed 77 per cent., 81.5 per cent., and 92.25 per cent. respectively, of protected cases. It is concluded that, although the anti-rachitic value of irradiated ergosterol increases according to its vitamin D content, this value is less than that of cod-liver oil containing a smaller amount of vitamin D units to the daily dose. The chief impression drawn from the observation is that the greater efficacy of cod-liver oil is due to the presence of vitamin A as well as D, and that in the present-day enthusiasm for concentrated and synthetic vitamin compounds, the merits of well-proved natural products should not be overlooked.

Surgery

444 Ureteral Strictures

W. MULVEHILL (*Amer. Journ. of Surg.*, August, 1931, p. 256) considers that urethral stricture is a more common disease than is sometimes recognized. Some cases show pathological signs of ulceration with little scar tissue; others present earlier stages of inflammation. Some cases show a full and complete scarring when the blockage is almost entirely due to the contraction of the scar, and only slightly to the active swelling resultant from the inflammation. Pathological end-results of ureteral stricture are ureteral and kidney stasis with infections above the stricture. Conditions which may be due to ureteral stricture are hydronephrosis, essential haematuria, pyonephrosis, pyelitis, urinary calculi, and some medical nephritides. The causative factors in most cases of stricture are the common pyogenic organisms such as *B. coli*, the staphylococcus, and the streptococcus. Hematogenous infection from the appendix, tonsils, teeth, or gall-bladder is responsible for the majority of cases. The most important symptom is a dull aching pain, which is not definite or intense in character, and may occur in the lower right or left quadrant of the abdomen, near the umbilicus or higher in the back. Backache, frequency of micturition, and menstrual pain are other symptoms which may be present. Treatment by dilatation of the strictured ureter is an effective method of dealing with the condition, and has proved completely successful in 50 per cent. of cases, giving relief for varying periods in a much higher percentage of cases. Dilatations may be repeated if necessary.

445 Removal of Tonsils by Diathermy

A. L. FORSTER (*Med. Journ. and Record*, September 16th, 1931, p. 290) advocates the use of diathermy in the extraction of tonsils. Specific indications for removal are: recurrent attacks of tonsillitis, chronic enlargement, fibrosis, and infection; diseases of the pharynx, trachea, and bronchi; enlargement of the cervical glands; laryngitis with attacks of hoarseness; diseases of the ear, nose, and accessory sinuses; suspected or incipient tuberculosis; arthritis, synovitis, and neuritis; gastro-intestinal derangements, general debility, and neurasthenia. The advantages of the diathermy method are that it is safe, clean, and effective; it does not necessitate hospitalization or loss of work for the patient. No general anaesthetic is required. The procedure is rendered painless by the application of cocaine to the throat, and it is seldom followed by more than trifling discomfort. There is no ss calculated, which is an obvious advantage in haemo- periods. He ose suffering from any condition in which obsolescence would be harmful. There is no danger of ance does he n any effective material is destroyed at the the wear-and-tear secondary infection is impossible, since

*** Obsolescence ng points, and there is no possibility penses of the year ctive matter into the lungs. Recur- prepared. As March consil never occurs when the proper technique is employed, since a sufficient number of applications for complete electro-coagulation can be made. There being no actual cauterization of tissue, no sloughing occurs, and there is no resulting mutilation of the throat. When the removal is performed in stages, four or five applications usually suffice, but both tonsils can be entirely removed at one sitting.

446 Diphtheria following Tonsillectomy

G. BISMUT (*Thèse de Paris*, 1931, No. 452) records eight cases in children, aged from 2 to 9 years, showing that diphtheria may take place a few days after removal of tonsils and adenoids when no preventive inoculation has been carried out. This occurrence is by no means rare, and the attack may be severe, partly owing to the difficulty of diagnosis, but mainly because of the rapid and early absorption of toxins by the operation wound. Children, therefore, should undergo preventive inoculation before being submitted to tonsillectomy and adenoidectomy. In the case of carriers a Schick test should be performed. If the reaction is negative the operation may be performed without any risk, but if it is positive, the child should undergo active or passive immunization.

447 Carcinoma in Osteomyelitis

That carcinoma may develop in old ulcers and sinuses has been known for many years, but has been little reported recently. E. B. BENEDICT (*Surg., Gynecol. and Obstet.*, July, 1931, p. 1) states that, though carcinoma is an extremely rare complication of osteomyelitis, only twelve cases having occurred in 2,400 of osteomyelitis at the Massachusetts General Hospital, the lesion is well defined, and important to recognize. In the twelve cases here recorded, the tibia was affected in eight, the foot in three, and the femur in one. Involvement of the jaw, humerus, or other scattered locations was not found. The complication is more common in males. In about half the cases, pain is a prominent symptom; not infrequently trauma has preceded the onset of the osteomyelitis. Usually surrounding the fistulous opening there is a cauliflower mass, easy of diagnosis; when the disease is deep-seated, its recognition is impossible until the osteomyelitic cavity has been explored and a biopsy performed, which should be done in all suspicious cases. Since the growth is ordinarily of the slowly developing epidermoid variety of low malignancy, and there is usually no metastasis in the groin, the prognosis is generally favourable. Treatment comprises prophylaxis, not permitting osteomyelitic sinuses to remain open indefinitely, and curative measures—namely, amputation in most cases.

448 Fat Embolism

B. M. VANCE (*Arch. of Surg.*, September, 1931, p. 426) describes fat embolism as a condition which occurs when a liquid oil enters the circulating blood, and is carried in globules large enough to obstruct the lumen of blood vessels in different parts of the body. There are two varieties of fat embolism: the pulmonary form in which the emboli obstruct the small blood vessels of the lungs, and produce symptoms of asphyxia; and the cerebral form in which the emboli enter the arterial circulation, block the arterioles in the organs, particularly in the brain, and produce symptoms referable to the central nervous system. The most general cause is some form of trauma, either to the adipose tissue or to the osseous system. In the latter case the trauma may be due to fractures, jarring of the skeleton, or orthopaedic operations. Trauma to the fatty viscera may also cause fat embolism. Most of the cases of fat embolism are either so slight that they do not cause symptoms, or so severe that death ensues in a few days from involvement of the lungs or brain. Fat embolism is therefore rarely diagnosed from clinical signs, and is most frequently discovered at the necropsy. There is no successful method of treatment; after the fat has entered the blood stream the result must be left to the natural defences of the body. The danger of the occurrence of fat embolism in the case of fractures can be lessened by the effective immobilization of the broken bones, which minimizes the passage of fat

into the venous circulation. In orthopaedic cases an Esmarch bandage may be used to obviate the transference from the operative site of an excessive amount of fat into the systemic veins. Severe fat embolism of the pulmonary type usually occurs in the first two days after the injury, and is referable to a marked obstruction of the arterioles and capillaries of the lung, with death from asphyxial symptoms. The emboli may pass through the pulmonary capillaries into the systemic circulation, and originate lesions in the brain, heart, and other organs. In this type of cerebral fat embolism death usually occurs in from two to seven days after the involvement of the nervous system.

449 Recovery from Generalized Streptococcal Infection

C. E. HAINES (*Journ. Amer. Med. Assoc.*, August 29th, 1931, p. 610) records a case, in a male infant aged 6 months, of peritonitis due to a haemolytic streptococcus and epididymitis secondary to streptococcal tonsillitis. Recovery followed laparotomy, but was delayed by the occurrence of purulent pleurisy which was treated by aspiration. Cultivation of the peritoneal and pleural pus showed the presence of *Streptococcus haemolyticus*.

Therapeutics

450 Treatment of Atophan Poisoning

K. EIMER (*Deut. med. Woch.*, September 25th, 1931, p. 1663) records the case of a man aged 52, who received large doses of atophan (118 grams in 41 days) on account of chronic rheumatism. During the treatment he became very ill; there followed severe jaundice, with tenderness and enlargement of the liver, and a rash which in places was definitely haemorrhagic. The urine contained bilirubin, and a trace of albumin, but no urobilin, tyrosine, or leucine. The faeces were pale, and contained no bile or hydrobilirubin. The coagulation time of the blood was somewhat increased (7 minutes), the bleeding time being normal. The van den Bergh test gave a positive direct reaction. During the period of serious illness the nitrogen excretion was very high (15 to 18 grams daily), denoting a marked breakdown of tissue proteins. As soon as the symptoms developed, atophan administration was discontinued, and 60 grams of dextrose and 20 units of insulin were given twice daily. Later on, duodenal lavage with magnesium sulphate solution was also instituted. The patient slowly recovered. The author mentions the serious outlook in these cases, as judged by the fatalities recorded. He believes that the energetic treatment used in this case was connected with the favourable result. The necessity for caution in the use of atophan, and particularly for frequent rest periods during treatment, because of the danger of accumulation, is also emphasized.

451 Pyrexial Treatment of Chorea

LUCY P. SUTTON (*Journ. Amer. Med. Assoc.*, August 1st, 1931, p. 299) records a case of the cure of chorea following accidental toxic pyrexia due to phenobarbital, prescribed as a sedative. A choreic boy aged 11 was speechless, helpless, and in constant violent movement. After eleven days the drug produced a generalized morbilliform eruption with moderate fever, but on one occasion the temperature rose to 106.4° F. After a few days the choreic movements diminished continuously, and in twenty-seven days the speech had become almost normal, the movements were only slight, and the boy gained strength rapidly. A week later he was free from all symptoms. He recovered from the drug intoxication without complications and remains well. Phenobarbital had been used previously in many cases of chorea with little benefit and without toxic symptoms, and it appeared that cure in this particular case was due to the fever. To solve this problem, daily intravenous injections of a mixed typhoid and paratyphoid vaccine were given to twenty-four choreic patients in a period of nearly two years, injections of malarial blood being considered too dangerous. The initial dose of vaccine was 0.2 or 0.25 c.cm. A sharp reaction followed; in one case the temperature was 107° F.; a smaller initial dose is therefore preferable. If the temperature rises to 105°–106° F., the same dose is repeated next day, and the third dose usually causes a feebler reaction. A dose of 2.5 c.cm. has been given in the later stages. Rigors commence about twenty minutes after the injection, with malaise and increased choreic movements. The temperature reaches its maximum in two to four hours, and falls to normal in six to eight hours. When the temperature rises to 105°, 5 grains of aspirin are given. Cyanosis occurs occasionally, but otherwise no ill-effects have been observed. The course of the chorea is a guide to the continuance of the treatment; pyrexia of one week's duration usually suffices. The average duration of choreic symptoms after vaccine treatment has been eight or nine days, whereas the average duration in 63 cases not so treated was forty-seven days. The author considers that this treatment has been more satisfactory than any other.

452 Calcium in Diphtheria

E. KAESPER (*Arch. f. Kinderheilk.*, September 11th, 1931, p. 205), in addition to the early injection of antitoxin, recommends the administration of calcium in laryngeal diphtheria, where it is specially indicated owing to its action on the oedema of the larynx. He also commends it in the treatment of severe cases of diphtheria, accompanied by the presence of extensive membrane, collateral oedema, and swelling of the regional cervical glands. The earlier the calcium is given, the better the effect. In the acute stage 5–10 c.cm. of the preparation of Sandoz was injected once or twice daily intramuscularly. After the acute symptoms had subsided, the calcium treatment was continued in the form of powders or tablets taken by the mouth. The action of the calcium is threefold; it dispels the oedema, is a cardiac tonic, and prevents or mitigates serum sickness.

453 Desiccated Whole-Hog Stomach in Anaemia

As the result of the administration of desiccated, defatted whole-hog stomach in fifteen patients, A. B. BROWER and W. M. SIMPSON (*Amer. Journ. Med. Sci.*, September, 1931, p. 319) conclude that this substance in adequate dosage is effective in producing a prompt and continued remission in cases of pernicious anaemia. A striking subjective improvement occurs in four or five days following the initial administration of the stomach powder; reticulocytosis reaches its peak in seven to nine days, after which the percentage of reticulocytes rapidly drops to the normal. Mild neurological symptoms, noted in eight patients, disappeared or were distinctly alleviated. The administration of dilute hydrochloric acid in association with the stomach powder is apparently unnecessary; stomach and liver therapy have eliminated the need for repeated transfusions. The optimum daily dose is 30 grams, and the daily maintenance dose is 10 grams. The powder may be given as a suspension in tomato (preferably) or any fruit juice. Occasionally patients may be found to respond more satisfactorily to stomach than to liver therapy. Subjects of advanced age may require larger doses than middle-aged ones. No aversion to the continued use of the desiccated stomach was noted, and the necessity of continuing treatment throughout the remainder of life must be impressed on the patient.

454 The Ketogenic Treatment of Epilepsy

C. BASTIBLE (*Irish Journ. Med. Sci.*, September, 1931, p. 506) reports a series of 29 cases of epilepsy, mostly of the grand mal type in adult females, which were treated for six months by the ketogenic diet, which is rich in fat, and poor in carbohydrate and protein. All these patients were so unmanageable as to be unfit to remain in their own homes. The typical daily diet was the equivalent of 2,128 calories; it included biscuits made from bran and "Carrigeen moss," an inexpensive seaweed found off the Irish shores, in order to enable the large amount of fat to be taken. In twenty cases there was a definite reduction in the number of fits, and complete cessation was induced in two by the end of the first

month. The addition of acid salts to the diet during the last two months, combined with some restriction of the fluid intake, seemed to have a definitely beneficial effect in still further reducing the number of seizures. In four cases presenting evidence of organic degeneration of the brain there was a substantially increased incidence of fits while the patients were on treatment. In several instances there were ketonuric interruptions, and a definite increase in the number of epileptic fits was noticeable when ketones were absent from the urine. Bastible considers that these results indicate that the ketogenic treatment, which is admittedly valuable in the epilepsy of childhood, is well worth more extended trial in the adult types of the disease, especially since all the other therapeutic measures are ineffective, and often cause definite organic degenerative changes to occur or increase. He adds that the diet should be continued for twelve months, even though the seizures have been controlled. The gradual return to a normal diet is made by first decreasing slightly the fat and increasing the protein, and then by still further diminishing the fat intake and adding a little carbohydrate in place of the saccharine previously employed. Epileptic patients should in any case avoid excessive amounts of carbohydrate, and keep their diet near the borderline of ketosis.

Radiology

455 Specification of X-Ray Quality

R. B. WILSEY (*Radiology*, October, 1931, p. 700) cites reasons for considering that tube voltage, the penetrometer scale reading, half value layer, effective or average wave-length, and the absorption coefficient, though all useful in themselves, are each inadequate as a general specification of quality of *x* rays. Thus the same effective wave-length, or absorption coefficient, can be produced by a wide range of combinations of tube voltage and filtration, but the corresponding radiations are not equivalent in their absorption and photographic effects. A homogeneity coefficient, derived from absorption data, can be used in addition to the absorption coefficient to define radiation quality more completely, but its determination is rather involved for routine purposes. Wilsey describes how the absorption curve (log I or I/Io, plotted against filter thickness) can be employed as a general specification of *x*-ray quality, being uniquely related to the spectral distribution of *x*-ray intensity, and discriminating more accurately than other methods of quality specification between different qualities of *x* rays. It distinguishes radiations having appreciably different degrees of absorption in tissues, and probably is sufficiently precise for quality variations differing measurably in biological or photographical effects. It is a simple form of expression, avoiding complicated calculations, and the principal characteristics of the radiation can be readily interpreted by inspecting the curve. Other methods of *x*-ray quality specification—such as half value layer, absorption coefficient, or effective wave-length, and homogeneity coefficient—can be derived from the absorption curve, and further research will probably indicate how additional information of value can be obtained from it.

456 Radiographical Diagnosis of the Pyelonephritis of Pregnancy

R. MAHON and R. GUICHARD (*Journ. de Méd. de Bordeaux*, September 20th–30th, 1931, p. 795) believe that a series of radiographs taken after the intravenous injection of urosclectan constitutes the method of election for exploring the urinary apparatus during pregnancy. It has the great advantage of revealing the exact anatomical and of the urinary passages without any artificial dilatation. The technique is simple; 70 to 100 c.cm. of urosclectan (30 grams of the salt dissolved in 70 grams of water) is injected intravenously into the patient lying on the *x*-ray table. Radiographs are obtained after a quarter of an hour, half an hour, one hour, and one and a half hours, respectively. Very little inconvenience is caused, and painful uterine contractions have never been observed in women near term. Results obtained from the comparison of normal pregnant women with those suffering from pyelitis showed that certain anatomical and functional modifications of the kidney pelvis and ureter occur in normal women; these may be dilatation, atony, or stasis. They are invariably more marked on the right side, and it is suggested that a foetal shoulder may be the cause of the compression. Such lesions would naturally favour the localization and development of bacillary infections, and therefore an examination with urosclectan does not eliminate the need for the usual bacteriological investigations.

457 X-Ray Treatment of Graves's Disease

O. SANDSTRÖM (*Nordisk Medicinsk Tidskrift*, May 23rd, 1931, p. 330) reviews the activities of Professor Forssell's institute, "Radiumhemmet," in Stockholm, with special reference to the 117 cases of Graves's disease admitted in the period 1918–28. Adequate after-histories were obtained in 92 of these cases; 43 patients completely recovered and became fit for work, while in 19 fitness for work with considerable improvement of health was achieved. There were 9 cases in which considerable improvement was effected without full capacity for work being restored. Twelve patients were neither better nor worse, and 7 had relapsed after considerable improvement had been effected. Two of the patients had died. *X*-ray treatment soon induces a subjective sense of improvement, but three or four months usually pass before definite objective improvement is demonstrable; the patients who recover completely usually take a year or two to lose all their symptoms. *X*-ray treatment does not, as has been suggested, spoil the chances of subsequent operative treatment by provoking adhesions; and provided that time is allowed for the hyperaemia of *x*-ray treatment to pass off, the surgeon will not be inconvenienced by it. The treatment occasionally increases the basal metabolism at the beginning, but the author has seen no case of prolonged disturbances of the metabolism traceable to this treatment. With regard to the comparative merits of *x*-ray and operative treatment, the field for the former would seem to be represented primarily by slight cases, and by those moderately severe cases in which it is possible for the patient to afford a treatment which takes long to be effective. Suitable for *x*-ray treatment are also most of the severe cases in which, for some reason or other, an operation is contraindicated. Some of these cases may be rendered operable by a preliminary course of *x*-ray treatment. The patient who refuses operation, or for whom other forms of treatment have failed, may also be recommended *x*-ray treatment.

Obstetrics and Gynaecology

458 Etiology of Endometrial Hyperplasia

The exact etiology of idiopathic uterine bleeding has not been determined, although a hypothesis of deficiency of the corpus luteum, first proposed by Schroeder, has been advanced. J. C. BURCH, W. L. WILLIAMS, and R. S. CUNNINGHAM (*Surg., Gynecol. and Obstet.*, September, 1931, p. 338) present an experimental analysis in which curetted material from 28 cases of prolonged uterine bleeding, and from patients with normal menstrual histories, was histologically examined; the effects produced by extracts of placenta and corpus luteum in spayed mice were also studied. The outstanding facts which correlate the menstrual cycle of the human with the oestrual cycle of experimental animals are briefly reviewed. The results of this study indicate that each of the oestrin and corpus luteum hormones exerts a definite characteristic action on the endometrium. The histology of the endometrium in Swiss cheese hyperplasia closely resembles that found in animals injected with placental extracts. This hyperplasia is due to an excess of oestrin acting on the endometrium, and bleeding takes place without the formation

of a corpus luteum. The failure to ovulate is probably an important factor in the disease, closely connected with the hypophyseal function. Extracts of corpus luteum might benefit this condition. In cases with mixed effects, it is possible to determine histologically which is predominant. Material from the follicular cysts of human cases of hyperplasia produced oestrus in mice and rats; the uterine changes in each case were very similar to those found in the animals.

459 Detection of Early Cervical Cancer

HAMANT and KOENIG (*Gynécol. et Obstét.*, September, 1931, p. 299) review the social methods which can be adopted in order to discover cancer of the cervix in its early stages. The perfecting of surgical technique and treatment by radium and *x* rays permit a high percentage of cures, but unfortunately, some 50 per cent. of women do not seek advice until the lesion is already well advanced. Analysis of the causes of delay between the appearance of the initial symptoms and the diagnosis and treatment shows that patients postpone obtaining advice from ignorance or fear; medical practitioners too often make an insufficient examination; and midwives, through ignorance, perform illegal operations, causing trauma, and give unwise reassurances. Emphasis is laid on the importance of the complete vaginal examination with speculum; if there is the least suspicion about the presence of malignancy, tissue should be removed for histological examination. A purely symptomatic anodyne should never be given in doubtful cases, or without complete examination. Midwives should be instructed in the schools, and in special courses, with regard to the danger of giving gynaecological advice, and it is added that the same applies to chemists. Periodical examinations of women would reveal some early cases of uterine cancer, and might well be systematized. Special watch should be kept in cases of abortion; metritis should be treated. The authors describe a scheme of co-ordinating existing gynaecological and cancer clinics with public health institutions and special preventive centres. They add that more needs to be done to suppress charlatanism and promote education of the public in the prophylaxis of malignant disease.

460 Clinical Features of Pelvic Endometriosis

T. CUZZA (*Riv. d'Ostet. e Ginecol. Prat.*, August, 1931, p. 328), while conceding that no sign or symptom is pathognomonic of intrapelvic endometriosis, holds that a pre-operative diagnosis is sometimes possible. The most constant symptom is dysmenorrhoea, experienced secondarily in adult life. It is very severe, and very resistant to treatment, and is sometimes accompanied by vomiting or rectal or vesical tenesmus. With cessation of the flow, the pain, which has not diminished previously, vanishes abruptly. A moderate degree of menorrhagia is usual, and married patients report dyspareunia. The uterus is somewhat enlarged and has a highly characteristic soft, elastic consistence; it may be retroflexed and may contain one or more myomata. When the ovaries are the site of endometriosis they are found to be moderately enlarged, fixed, and tender. The pelvic connective tissue, especially in the pouch of Douglas, is rigid, although nothing in the history or present signs points to pelvic inflammation.

461 Tuberculosis of the Genitals

B. WALLER (*Zentralbl. f. Gynäk.*, July 18th, 1931, p. 2215), who records a personal case, states that, according to the findings in the Anatomical Institute at Brünn, at least 2 per cent. of all diseases of the female genitals are caused by tuberculosis. The rarest form is isolated ovarian tuberculosis. As a rule all parts of the internal organs are affected, the tubes being most frequently involved. The cervix is very rarely attacked, since the mucous membrane is more resistant, and the os internum offers an obstruction to the extension of the process. According to Krönig the uterus alone is affected in 11 per cent. As regards age, the disease may occur at any period, but is commonest at puberty. Infection of the female genitals may be explained in three ways: (1) haematogenous and lymphogenous infection, which accounts for the majority of cases; (2) direct and continuous spread of the infection from the peritoneum and urinary system; and (3) cryptogenic infection. In such cases tubercle bacilli are introduced by the semen, or by injuries to the vagina. Waller's patient was a woman, aged 47, who was sterile although she had been married for 25 years; she was suffering from metrorrhagia. Curettings of the uterine mucosa contained necrotic tissue and typical Langhans's giant cells. Laparotomy revealed advanced tuberculosis of both Fallopian tubes; these were removed, together with the uterus, which showed signs of specific endometritis. The patient made a good recovery, and had gained 6 kilos in weight when seen three months after the operation.

462 Thyrotoxicosis Complicated by Pregnancy

Discussing thyrotoxicosis complicated by pregnancy, A. J. FLEISCHER (*Amer. Journ. Obstet. and Gynecol.*, August, 1931, p. 273) states that this form of hyperthyroidism may be entirely secondary to the pregnancy, or a latent case of the disease may be suddenly activated by the growth of the foetus. A case is reported in which the patient, a 2-para, dated back her history of thyroid disease to the commencement of puberty. This thyroid syndrome, which was at first very mild, became alarmingly intensified during the first pregnancy. It recurred during the second one, and, owing to the progression of unfavourable symptoms, pregnancy was terminated at 8½ months by laparotrachelotomy. The opinions of Beck and Seitz on this condition are cited. Fleischer deems the following as essential in the ante-partum care of pregnant women suffering from Graves's disease: absolute rest, sedatives being given if necessary; improvement of the hygienic conditions; and dietetic correction, proteins being excluded as much as possible. Where labour is spontaneous, shortening of the second stage by forceps is advised. Where it becomes necessary to terminate pregnancy as an emergency measure, the best procedure is laparotrachelotomy under spinal anaesthesia, preceded by morphine and scopolamine. Cases of hyperthyroidism so severe as to require emergency measures should also be sterilized.

463 Squamous Epithelium and Mucous Cervical Polypi

G. MOGLIA (*Ann. Ostet. e Ginecol.*, June 30th, 1931, p. 681), from examination of seventy-two mucous polypi of the cervical canal, concludes that metaplasia is a causative factor that plays a considerable part in epidermatization of the surface, which was present in fifty cases. This metaplasia begins in those cells of the cylindrical epithelium (of the surface or of the glands) which are just within the basement membrane. The squamous epithelium, thus formed, is found in multiple unconnected islets from which mitoses are absent. Metaplasia may extend along the cervical canal, so that after the removal of a polypus it is prudent to scrape its site of insertion, and the endocervical mucous membrane.

464 Limitations of X-Ray Therapy in Pelvic Tumours

J. C. BLOCH and BROSIO (*Bull. Soc. Obstét. et Gynécol. de Paris*, July, 1931, p. 517) describe a case which illustrates the histological changes which may be produced in an ovarian cyst by exposure to *x* rays. The patient, aged 60, had suffered from menorrhagia for six years. Brosio found a voluminous pelvic tumour, which he diagnosed as a fibroma, and advised operation. The patient refused consent, and a radiologist gave her a course of radiotherapy. At the end of four months the haemorrhage had completely ceased, but other troubles continued and increased. The patient was obese, had varicose veins, and suffered from alternate dysuria and polyuria with chronic fatigue. A year later Brosio found that the tumour had increased in size and was now fixed. Bloch performed a supravaginal hysterectomy, and the patient made a good recovery, except for some trouble from vascularization of the skin round the scar, attributable to the *x* rays. The tumour proved to be a bilateral ovarian cyst, particularly noteworthy because of superficial vegetations which partly covered the cyst on the

right side. Histological examination showed that these vegetations appeared benign, but their presence necessitated a guarded prognosis. Bloch suggests that they were caused by the *x*-ray treatment, and concludes that, when there is any doubt in the surgeon's mind whether a fibroma or cyst is present, an operation should be advised ; *x*-ray treatment should not be offered as an alternative. Radiotherapy in such a case is at least a risk, and serves no good end. In addition, a train of disorders, such as adhesions, cutaneous troubles, and vegetations, may be produced. *X* rays should only be used when the diagnosis of fibroma is precise and certain.

Pathology

465 Mode of Action of Anti-tetanic Serum

Though the prophylaxis of tetanus is sufficiently assured by subcutaneous injections of anti-tetanic serum, the curative efficacy of this method of administration is not unanimously accepted. S. Muetermilch and Mlle. E. Salamon (*Ann. de l'Inst. Pasteur*, September, 1931, p. 277) relate a series of experiments on rabbits which prove that meningeal injections (intracerebral or subarachnoid) are far superior to those made by the subcutaneous and intravenous routes. This method, first advocated by Roux and Borrel, not only causes a local production of specific antibodies, but also ensures their appearance in the blood in larger amounts than by other measures. These meningeal injections are well tolerated. The addition of tetanic anatoxin to the serum is most beneficial ; it produces an immediate neutralization of the toxin by the antitoxin, and a rapid active immunization of the organism. According to Dufour the injections are more active when given under chloroform anaesthesia. The mechanism of the favourable action of meningeal injections is discussed, three hypotheses being enumerated as regards the possible site of neutralization of the toxin ; it may be effected in the subarachnoid space, the peripheral nerves, or in the cells of the central nervous system. The authors believe the last-named to be the site, and state that antitoxin, inoculated meningeally, acts in two ways: it is fixed immediately by the nerve cells and destroys the toxin *in situ*, and, being resorbed into the general circulation, it neutralizes the toxin fraction present in the blood.

466 The Transmission of Typhus Fever

R. E. Dyer *et al.* (*United States Public Health Reports*, August 7th, 1931, p. 1869) describe an investigation designed to throw further light on the intimate association of the spread of typhus fever with the rat flea, *Xenopsylla cheopis*, the importance of which in this respect was clearly indicated by a systematic examination of wild rats trapped in Baltimore at typhus fever centres. White rats injected with endemic typhus virus were brought into contact with fleas of this species ; about two weeks later six fleas were removed from the cage, emulsified in normal saline, and injected into two guinea-pigs. One guinea-pig developed clinically endemic typhus, and this strain was continued in guinea-pigs and rabbits for three generations. Similar experiments were then made with other rats and rabbits ; guinea-pigs were successfully inoculated and developed typhus fever. The blood and organs in all cases were examined, and the specific agglutinins were always found to be present. Guinea-pigs which had recovered from an infection with an established strain of endemic typhus virus originally derived from a human case, and also guinea-pigs which had survived infection with endemic typhus virus isolated from rat fleas caught at typhus centres, were found to be immune to subsequent inoculations with the strains of virus recovered from infected fleas, and also to other strains obtained from rats. Careful repeated search of the cages and rats failed to show the presence of any blood-sucking parasite other than *Xenopsylla cheopis*.

467 Two Forms of the Diphtheria Bacillus

J. S. Anderson, F. C. Happold, J. W. McLeod, and J. G. Thomson (*Journ. Path. and Bact.*, September, 1931, p. 667), working at Leeds, describe the existence of two forms of diphtheria bacillus. The one variant, which they call *gravis*, grows with granular deposit and pellicle in broth, has a flattened lustreless colony of irregular outline, and actively ferments dextrin, starch, and glycogen ; it is associated with severe toxic cases of the disease. The other, which they call *mitis*, grows with uniform turbidity in broth, has a convex, partly translucent, glistening colony, ferments dextrin inconstantly, and has no action on starch or glycogen ; it is associated with milder cases of the disease. A small proportion of intermediate forms with constant characteristics have been encountered. The differentiation of the two main forms is most easily accomplished on a special chocolate agar medium containing potassium tellurite, and made up with beef infusion that has been sterilized by filtration instead of by heat. In an examination of 104 cases of diphtheria, 63 were found to be due to the *gravis*, 35 to the *mitis*, and 6 to the intermediate type. It is significant that all the 11 fatal cases were associated with the *gravis* type, and that 14 out of the 17 cases showing paralysis were due to this type, the remaining three being due to the intermediate type. As regards virulence, *gravis* strains were almost invariably endowed with some degree of virulence, while *mitis* strains were not infrequently avirulent to guinea-pigs.

468 The Gonadotropic Hormones

The well-known divergent effects following injections of various extracts of the anterior pituitary lobe, placenta, and pregnancy urine have been ascribed to the presence of two hormonic factors, ρ_1 and ρ_2. It has been assumed that they occur in varying proportions, and that both their relative concentration and their absolute quantity are concerned in determining the sequel ; ρ_1 is considered to be responsible for the first phase of ovarian secretion. B. P. Wiesner and P. G. Marshall (*Quart. Journ. Exper. Physiol.*, August 12th, 1931, p. 147) discuss the properties and effects of the ρ factors, or gonadotropic hormones, and describe two methods (by phosphotungstic acid and alcohol precipitation) of preparing potent extracts containing them from the urine during pregnancy, and also from the anterior pituitary lobe and human placenta. It was found that prolonged injections of small quantities, or fewer injections of large quantities, of ρ factors inhibited the oestrous cycle in mature mice, while small quantities actually induced premature oestrus in immature animals. A theory is advanced to account for these phenomena, and various chemical properties, in accordance with the observations of other workers, are recorded. A comparison is suggested in this respect between them and the polypeptides. These factors are not destroyed by pepsin, but they are inactivated by trypsin.

469 Red Cell Sedimentation Rate in Gonorrhoea

E. Kiene and E. Hammerschmidt (*Wien. klin. Woch.*, August 7th, 1931, p. 1023), using the method and apparatus of Westergren, have studied the red cell sedimentation rate in 300 different gonorrhoeal patients who were classified in 5 groups: (1) slight chronic or abortive cases ; (2) gonorrhoea without deep tissue inflammation ; (3) cases complicated with lymphangitis and epididymitis ; (4) patients with gonorrhoeal arthritis ; (5) cases with gonorrhoeal myocarditis. It was found that, after excluding other diseases, the acceleration of the sedimentation rate in cases of gonorrhoea is proportional to the severity of the case ; in abortive or chronic cases with only slight inflammatory symptoms there is no acceleration of the sedimentation rate. During convalescence the raised sedimentation rate returns to the normal value, though it is always possible for an acute infection to become chronic, or the patient to be a gonorrhoea carrier. The sedimentation reaction precedes the clinical determination of inflammatory processes, and serves as a therapeutic guide.

A NEW QUININE SALT

Quinine Bi-Salicylo-salicylate

described for convenience as "QUINISAN" (Howards)

QUINISAN (Howards) is a definite chemical compound, occurring as a white odourless crystalline powder, practically insoluble in water. One 4-grain Quinisan tablet yields the approximate equivalent of 2 grains of quinine and 2½ grains salicylo-salicylic acid. It has proved very valuable in the treatment of influenza, coryza, tonsilitis, etc., and has the unusual property that the salicylo-salicylic acid content is not hydrolised until it has passed through the stomach to the intestines. The gastric irritation common with other salicylic preparations does not, therefore, arise.

According to eminent medical evidence 12 × 4-grain tablets of Quinisan, during 48 hours, gave remarkable results in influenza, the high temperature and shivering symptoms entirely disappearing by the next day, leaving the patient free from fever and discomfort by the afternoon.

Samples of QUINISAN (Howards) and literature will be sent to medical men on application, and supplies are now available through the usual wholesale channels.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro-Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

★ ★

"CELLANBAND"

PASTE BANDAGES

THESE bandages are Antiseptic Paste Impregnated according to the formula mentioned in the "B M J," October 4th, 1930. They exercise a marked dehydrating and antiphlogistic effect, leading to rapid reduction of oedema. When properly applied, a "Cellanband" Dressing is in many ways superior to crepe or rubber bandages, elastic hosiery, etc.

"Cellanband" Dressings, because of their many advantages, usually enable the convalescent to resume reasonable light duties at an earlier period than in the past.

A reputation—as well as a name

WHERE APERIENTS FAIL SURGICAL BELTS SUCCEED!

The introduction of X-ray photography has swept away many previously held conceptions of the pathology of the abdomen. This new method of examination has shown unmistakably that therapeutic measures such as the use of aperients and intestinal antiseptics are futile in the presence of mechanical displacements. It has revealed that the safe, scientific and effective measure in innumerable cases is to correct the mechanical fault in the engineering system of the abdomen by suitable upward support. Such support is given in specific complaints by Domen Surgical Belts.

Domen Surgical Belts provide ample support upwards from the pelvis. They counteract the downward pull of gravitation—the underlying cause of mankind's tendency to sag. And Domen Belts achieve this upward support without cramping or binding the patient. Domen Belts are light, and durable, and strong. On receipt of your card or a telephone request, full particulars will be forwarded.

The function of MARMITE in the treatment of skin affections

Medical Practitioners are invited to write for a sample of Marmite, together with full evidence of its usefulness. The Marmite Food Extract Co., Ltd., Walsingham House, Seething Lane, London, E.C.

A useful adjunct to the treatment of skin troubles is the addition to the diet of Marmite, the great Yeast Food extract. Marmite is one of the richest known sources of Vitamin B. It has been observed to stimulate the functioning of lymphoid tissue and may be relied on to improve appetite and digestion while counteracting intestinal stasis.

Marmite may be given in soups, sandwiches or sauces with fish, vegetables and all meat dishes.

Vapo-Cresolene Est. 1879

Sold by all Chemists

Write for descriptive Booklet No. 140.

ASTHMA

There are certain types of chronic asthmatics who require relief of their paroxysms. While adrenaline is generally effective, it must be given hypodermically, and its action is short-lived. Vapo-Cresolene (specially prepared cresols of coal tar), vaporized in the bedroom at night, will give the desired relief. The patient is not disturbed as he breathes the medicated air of the bedroom.

This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough, spasmodic croup.

'NEOTROPIN'

Urinary antiseptic and general internal disinfectant.

The remarkable power of penetration is a fundamental factor of its effectiveness.

SCHERING LTD., 3, Lloyd's Avenue, London, E.C.3.

Why the profession approves Mistol

FOR a number of years leading rhino-laryngologists have been recommending an oily spray solution containing menthol, camphor, eucalyptol and chlorbutol, for common cold, chronic rhinitis, hay fever, minor sore throats and lesser inflammations of the upper respiratory passages.

The makers of Nujol developed this suggestion so as to produce, after much scientific investigation, a product containing these ingredients in the form best suited for intranasal medication. Mistol was the result.

Administered with the dropper contained in each package, Mistol immediately spreads evenly over the nasal mucosa so as to form a thin protective film. It has the further property of clinging tenaciously, so as not to be dislodged by secretions. Further advantages of Mistol are that it may be taken as a gargle or nebulized into a fine vapour for inhalation.

Because its use is based on sound medical practice, Mistol enjoys the highest measure of professional approval and confidence.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales On the North West side of the Estate a mile of sea coast forms the boundary Patients may visit this branch for a short seaside change or for longer periods The Hospital has its own private bathing house on the seashore There is trout fishing in the park

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment

DOUGLAS MACAULAY, M.D., D.P.M.

TREATMENT of EARLY MENTAL CONDITIONS

Medical Men having cases presenting any of those numerous states of ill health and disability now more generally recognised as often primarily due to minor psychoses and neuroses and in need of investigation with view to decide on the treatment best likely to promote recovery and to prevent further mental deterioration, are invited to apply for particulars below, where for some years past a number of such cases, in both sexes, have been successfully dealt with

The number in residence at any one time being strictly limited, close individual attention can be given, whilst the patient is provided with a comfortable home life in pleasant surroundings, with suitable occupation for leisure hours

Certified cases and those definitely certifiable are not accepted.

RESIDENT PHYSICIAN, Elmsleigh, Bassett Southampton

BARNWOOD HOUSE,

GLOUCESTER.

A REGISTERED HOSPITAL for the CARE and TREATMENT of LADIES and GENTLEMEN suffering from NERVOUS and MENTAL DISORDERS. Within two miles of the G.W. Railway and L.M. & S. Railway Stations at Gloucester, the Hospital is easily accessible by rail from London and all parts of the United Kingdom. It is beautifully situated at the foot of the Cotswold Hills, and stands in its own grounds of over 280 acres. Voluntary boarders of both sexes are also received for treatment.

Special accommodation for Lady Voluntary Boarders is also provided at the MANOR HOUSE, which has its own private grounds and is entirely separate from the main Hospital

For particulars as to terms, etc, apply to—
ARTHUR TOWNSEND, M.D., Medical Supt.

HOME for Large grounds, 400 ft above sea ladies Mentally afflicted. Voluntary Boarders received. Station: Brentwood and Shenfield 1 mile. Liverp'l St 25 min.—Apply, Dr HAYES.

RUTHIN CASTLE, NORTH WALES

REDUCTION OF FEES

In view of the present economic position, the inclusive fees at Ruthin Castle, formerly from 17 guineas a week, have been reduced to from 15 guineas a week, beginning on October 19th, 1931.

The fees include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary x-ray examinations, and electrocardiograph readings; all treatment that may be prescribed, such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, nursing, medicines or vaccines, board and lodging.

The only extra charge is that for a complete alimentary x-ray examination, or for x-ray therapy.

Many people who would go abroad for health will not do so this winter. All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 29.5 inches, that is, less than the average for England. There is central heating throughout. Should the accommodation in the Castle not prove sufficient, comfortable rooms can be obtained near by for those undergoing treatment.

Address.—THE SECRETARY, Ruthin Castle, North Wales. *Telegrams*: CASTLE, RUTHIN. *Telephone*: RUTHIN 65

Full particulars, apply to: The Spa Director.

A MANIFESTO BY THE BRITISH SPAS FEDERATION

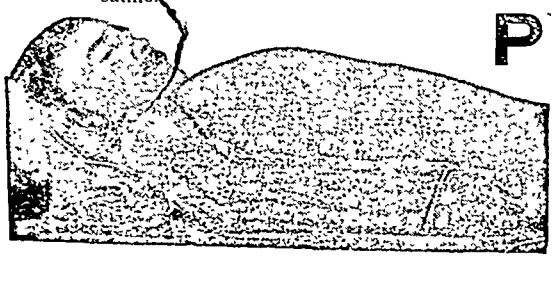
BATH · BRIDGE OF ALLAN · BUXTON · CHELTENHAM · DROITWICH · HARROGATE · LEAMINGTON · LLANDRINDOD WELLS · STRATHPEFFER · TREFRIW · WOODHALL · NEW ZEALAND

Keep money in the Country by sending your patients to a British Spa.

NO country in the world offers such a variety of natural mineral waters and Spa treatments as are available in your own country. The medical profession is assured of individual attention being given to their patients at the hands of trained staff.

Hotel tariffs are cheaper during the autumn and winter, and special diet can be arranged without extra charge.

Handbook and tariff charges with list of accommodation will gladly be sent on application to the Hon. Secretary, British Spas Federation, Pump Room, Leamington Spa, or the Manager of any of the Spas here mentioned.



BRITISH SPAS ARE BEST

THE TREATMENT OF RHEUMATOID ARTHRITIS

THIS disease, which the medical man is increasingly called upon to combat, may be successfully treated by the correct application of Pistany radio-active Mud Packs.

The packs can be applied in the patient's own home if necessary, and the treatment may be successfully combined with other physio-therapeutic methods.

Pistany (Czecho-Slovakia) offers the most effective treatment for the cure of rheumatoid arthritis. The properties of Pistany's hot volcanic soft mud are quite peculiar. During the season over 26,000 visitors go to this picturesque Spa, and statistics show that of 100% of patients, only less than 5% do not respond to the treatment—30% are completely relieved and 65% are considerably improved. Home treatment can never supersede the cure at the Spa.

All communications to be addressed to the Branch Manager, BRITISH MEDICAL BUREAU, 33, CROSS ST., MANCHESTER.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880)

12, Stratford Place,

Tele Address: Triform, Wesdo—London. Oxford Street, W.1. Telephone: Mayfair 1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads.—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUM TENENS.

Assistants and Locum Tenens can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Accounts, etc.

Premium £1,050.
5. MIDLANDS.—PARTNERSHIP.—A one-third share is offered in a very sound middle and working-class Practice, held by the senior partner for 35 years. Average gross cash receipts for the past three years nearly £3,000. Panel of over 1,600. Fees 3/6 to 21/-. Midwifery from 3 gns. (about 60 cases). Suitable house available on rental, with 2 reception, 3 bedrooms, etc. Small garden. Garage. Sport of all kinds, and very good schools within reach. Prem. 2 years' pur.
6. NORTH OF ENGLAND.—FAVOURITE COAST TOWN.—Old-established middle and upper-class non-panel PRACTICE, averaging for the past three years nearly £5,000. Fees from 5/- to 21/-. Very suitable for two friends in partnership, one holding the F.R.C.S., as there is excellent surgical scope. Two good houses available, with ample accommodation, either on rental, or by purchase.
7. MID-WALES.—Agricultural District.—Mixed-class PRACTICE, producing about £880 p.a., including small panel of 130. Fees 3/6 to 21/-. Small house, with 2 reception, 3 bedrooms, etc. Price £550. Fishing, shooting, and other sport. Premium 1 year's purchase.
8. WEST OF ENGLAND.—Old-established general PRACTICE, situated in exceptionally nice neighbourhood, with good sporting and social facilities. Income averages about £1,000 p.a., with small panel of 400. Fees from 3/6 to 1½ gns. Particularly good house, with beautiful garden, and containing 2 reception, 7 bedrooms, etc. Price for freehold £2,000, part on mortgage. Excellent surgical prospects. Premium 1½ years' purchase.
9. WOMAN DOCTOR'S PRACTICE.—YORKS.—LARGE TOWN.—Established eight years, easily worked, and producing nearly £700 p.a. Panel of 500. Fees 5/- to 7/6. Midwifery 3 to 5 gns. Compact house, with 2 sitting, 2 bedrooms, 4 attics, etc. Garden. Garage. Rent on lease £42 10s. p.a. Prem. 1½ years' purchase, or near offer.
10. SOUTH OF ENGLAND.—Favourite Coast Town.—NURSING HOME, with small private Practice combined, the latter offering very good scope for development. Total receipts last year about £600. Very nice detached house, with excellent accommodation, very well appointed. Price for leasehold (87 years to run) £2,100, or can be rented at £140 p.a. Premium for goodwill, to include handsome furniture, fittings, etc., £1,250.
11. MIDLANDS.—COUNTY TOWN.—PARTNERSHIP.—A one-fourth share is offered in an exceptionally sound good mixed-class Practice, averaging over £6,000 p.a., including panel of 3400. Lowest fee 4/-. Very little midwifery. If single, purchaser can live in comfortable rooms; otherwise choice of houses for sale or on rental. Premium 2 years' purchase.
12. NORTH OF ENGLAND.—GOOD TOWN.—A one-third share is offered in a very sound Practice, averaging about £5,000 p.a. Ingoing Partner must be well qualified and not over 35, and interested in medicine. Suitable house available. Premium 2 years' purchase.
13. CHESHIRE.—NEAR COAST.—Old-established middle and working-class PRACTICE, averaging for the past three years over £1,300. Panel of 550. Fees from 3/6. Good house, with 3 reception, 7 bedrooms, etc. Price for freehold £1,200, part on mortgage. Premium 2 years' purchase.
14. WITHIN TEN MILES OF LONDON. — PARTNERSHIP. — The third share of an old-established good middle and working-class Practice is for disposal, offering excellent future prospects. Cash receipts last year amounted to nearly £2,700, including panel of nearly 1,500. Suitable house available at moderate price. Premium £1,800.
15. WITHIN FOUR MILES OF THE BANK.—Old-established working-class PRACTICE, producing for the last 12 months £2,300, including panel of over 2,800. Appts. worth about £160. Visits from 2/6. Low expenses. Suitable house can be rented or bought. Surgery premises on rental. Premium £4,000 cash.
16. NORTH-WEST COAST.—SURGICAL PARTNERSHIP.—In a popular residential seaside resort the half share of middle and upper-class Practice is offered to a suitable gentleman possessing the F.R.C.S., as the retiring partner does the surgical work, the remaining partner the medical side. Receipts average nearly £5,000 p.a. Very good modern house, recently built, with ample accommodation, good garden, tennis court, etc. Rent on lease £240, or can be purchased. Premium 2 years' purchase.
17. PARTNERSHIP.—In a most desirable outlying residential suburb of London, a suitable partner (experienced, not over 30 years of age and married) can acquire a share producing (to commence with) about £1,200 p.a., in an old-established good mixed-class Practice averaging just over £10,000 p.a. Very good house, with ample accommodation. Rent £150 p.a. Premium 2 years' purchase cash.
18. MANCHESTER.—Good mixed-class PRACTICE, averaging over £1,300 p.a., but capable of much increase. Vendor having neglected work owing to ill-health. Panel of about 550. Fees 3/6 to 7/6. House, with 2 reception, 5 bedrooms, etc. Garden. Garage. Price £2,700. Premium 1½ years' purchase, payable by arrangement.
19. SOUTH AFRICA.—Within 100 miles of East London.—Increasing PRACTICE, in very pretty Township near sea coast, producing last financial year £1,066. Practically all fees cash. Climate excellent. No night work and little or no visiting. Living cheap. Bungalow residence in 3/4 acre of productive garden. Price £750, £400 on mortgage, or premium for quick sale £1,100 for Practice and house. Sport of all kinds.
20. BORDERS OF BERKS AND HANTS.—In a delightful sporting and agricultural district, within reach of market town, an old-established mixed-class PRACTICE averaging about £850 p.a., including panel over 400. Visits 5/- to 10/6, medicine extra. House contains 2 sitting, 7 bedrooms, bathroom, etc. Large garden. Garage. Rent £50 p.a. on lease. Premium £1,100.
21. DEVON.—PARTNERSHIP.—Half share of very old-established unopposed Country Practice, offering scope, and situated in pretty village within reach of large town. Cash receipts last year £2,220, including appts. and panel of 880. Visits 3/6 to 21/-, medicine extra. House contains 2 reception, 4 bedrooms, bathroom, etc. Garden. Garage. Rent £30 p.a. Premium £2,000. Hunting, shooting, fishing, etc.
22. MIDLANDS.—COUNTY TOWN.—PARTNERSHIP.—A one-third share (with increase to one-half later) is for disposal in a particularly sound well-established mixed-class Practice, owing to the retirement of the senior Partner. Gross cash receipts average £4,379 p.a. (last year £4,437). Panel of 1,344. Consultations 3/6 upwards. Visits 5/- to 21/-. Very suitable house, with 3 reception, 6 to 7 bedrooms, etc. Garden. Garage. Rent on lease £100 p.a. First-rate schools and sport. Premium 2 years' purchase.
23. NORTH DEVON & CORNWALL BORDERS.—Very old-established unopposed Country PRACTICE, in beautiful district near coast. Cash receipts average just over £1,100 p.a., including appt. and panel of 330. Suitable house available. Premium £1,600, to include drugs, etc. Hunting, golf, fishing, etc.
24. SOUTH OF ENGLAND.—Pleasant Town near Coast.—Very old-established middle and upper-class PRACTICE. Cash receipts average nearly £1,750 p.a., including panel of 500. Visits 3/6 to 21/-. Very little midwifery. House, including consulting room, waiting room, and dispensary, in well-situated part of town. Price, freehold, £1,500.
25. CATHEDRAL CITY (NORTH).—PARTNERSHIP.—Third Partner required in very old-established lucrative and increasing middle and working-class Practice. Cash receipts for past three years average £4,544 p.a. (last year £4,911), including panel about 4,000. A fifth share is for disposal, with increase to a third later. Suitable accommodation available. Premium 2 years' purchase.
26. NORTH MIDLANDS.—WITHIN 3 MILES OF FAVOURITE TOWN.—Old-established good middle-class PRACTICE, offering large scope. Cash receipts for last 12 months £1,332, including panel of over 1,000. Fees from 3/6. Mid. from 2 gns. Exceptionally nice house, in about 4 acres of ground, with tennis lawn, fruit and vegetable gardens, etc., containing 3 reception, 6 bedrooms, etc. Freehold for sale. Premium 1½ years' purchase.
27. MANCHESTER.—Semi-residential Suburb.—Very old-established non-dispensing mainly middle-class PRACTICE, averaging £2,500 p.a., including small selected panel of 440, which latter is capable of extension. Visits 5/- upwards. Only about 20 cases of Midwifery from 5 gns. Well-situated house, with good accommodation. Price (freehold) £1,600. Premium £3,750.
28. LINCS. — PLEASANT MARKET TOWN. — PARTNERSHIP. — A half share, with possible succession in two years' time. Average income for past three years £1,900, including appointments and panel producing £500. Advice and medicine 5/- upwards; visits from 5/-. Very few midwiferies from 2 to 3 guineas. Large house with garden and garage. Price freehold only £1,200. Sport of all kinds, and excellent schools for boys and girls. Premium 2 years' purchase, payable £1,000 down, remainder by arrangement.
29. LANCS.—LARGE TOWN.—Old-established better and middle-class PRACTICE, producing last year over £1,400, including panel of 970. Visits 2/6 to 10/6, with medicine extra. Suitable house, with 2 reception, 6 bedrooms, etc. Garage, garden. Rent on lease £90 p.a. Premium £2,050.

Full Schedule of Terms and Conditions will be forwarded on application.

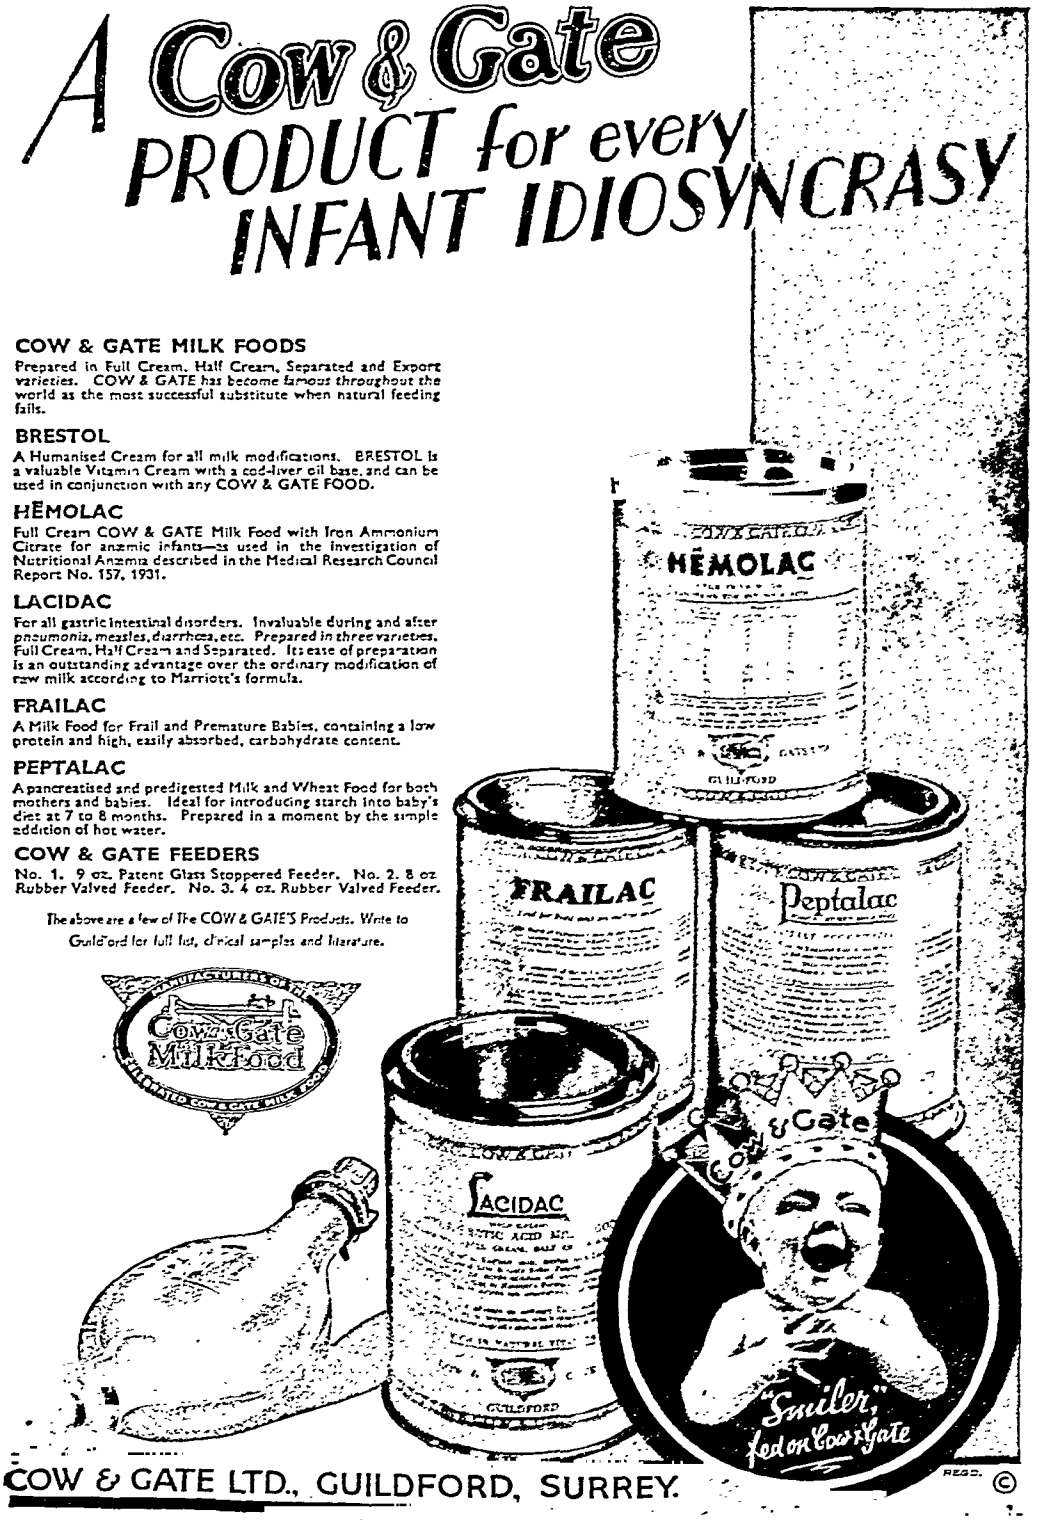
Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

A Cow & Gate PRODUCT for every INFANT IDIOSYNCRASY

COW & GATE MILK FOODS
Prepared in Full Cream, Half Cream, Separated and Export varieties. COW & GATE has become famous throughout the world as the most successful substitute when natural feeding fails.

BRESTOL
A Humanised Cream for all milk modifications. BRESTOL is a valuable Vitamin Cream with a cod-liver oil base, and can be used in conjunction with any COW & GATE FOOD.

HĒMOLAC
Full Cream COW & GATE Milk Food with Iron Ammonium Citrate for anæmic infants—as used in the investigation of Nutritional Anæmia described in the Medical Research Council Report No. 157, 1931.



LACIDAC
For all gastric intestinal disorders. Invaluable during and after *pneumonia, measles, diarrhœa, etc.* Prepared in three varieties, Full Cream, Half Cream and Separated. Its ease of preparation is an outstanding advantage over the ordinary modification of raw milk according to Marriott's formula.

FRAILAC
A Milk Food for Frail and Premature Babies, containing a low protein and high, easily absorbed, carbohydrate content.

PEPTALAC
A pancreatised and predigested Milk and Wheat Food for both mothers and babies. Ideal for introducing starch into baby's diet at 7 to 8 months. Prepared in a moment by the simple addition of hot water.

COW & GATE FEEDERS
No. 1. 9 oz. Patent Glass Stoppered Feeder. No. 2. 8 oz. Rubber Valved Feeder. No. 3. 4 oz. Rubber Valved Feeder.

The above are a few of The COW & GATE'S Products. Write to Guildford for full list, clinical samples and literature.

COW & GATE LTD., GUILDFORD, SURREY.

Prescribe British

Made entirely from English Beef

The "Allenburys" Beef Juice is prepared from prime, lean **English Beef** by a special process which conserves all the nutritive constituents and the vitamins in a natural, unaltered and assimilable form. The Juice of the fresh beef is extracted under pressure and concentrated in vacuo, a low temperature being maintained throughout the process to ensure that the albumens of the beef are not coagulated.

Price:

3/- per bottle

Literature and clinical trial sample will be sent on application.

PNEUMONIA—INFLUENZA CORYZA

is provided by

EDWENIL

A Polyvalent Antibacterial Agent.

A typical pneumonia report states:

"Male adult, admitted to hospital on the second day of illness, suffering from double lobar pneumonia. His condition appeared hopeless. He was very deeply cyanosed, pulse 140, respiration 48, temperature 103·2°.

"2 c.c. of Edwenil were given, followed by a fall in temperature to 99° in 12 hours. A second dose of 2 c.c. was given. Temperature rose to 102·4° and fell again in another 12 hours.

"This cycle was repeated and temperature reached normal on the 6th day. Six hours after the first injection, it was obvious that he was more comfortable. The cyanosis began to subside on the second day. From that time improvement was rapid and uneventful."

A 12½ c.c. or 25 c.c. bottle of EDWENIL will be enough to demonstrate its activity in your own practice.

NEW **ANDREWS'** *NEW*

DISEASES OF THE SKIN

THE BRITISH MEDICAL JOURNAL says:—

Amid the flood of textbooks of dermatology which have appeared within the last few years that by Dr. G. C. Andrews of New York, "Diseases of the Skin," stands out. It is certainly among the best. While it is of ample size adequately to deal with the subject, the author maintains the proper proportions between what it is important for all students and practitioners to know about the essentials of cutaneous medicine and those quaint and interesting rarities which appeal almost exclusively to the specialist, whose attitude towards them often resembles that of the collector of postage stamps towards unique specimens of the philatelic art. Dr. Andrews has brought his account of the subject thoroughly up to date, and in doing so has taken immense pains. There is no better evidence of this than the vast bibliography appended to each chapter, which shows how thoroughly he and his assistants, whose help he generously acknowledges in the preface, have searched the whole of dermatological literature for all that might be useful in this magnum opus.

A special word of commendation must be accorded to the illustrations, which are both numerous and excellent. In the volume of just over 1,000 pages there are nearly a thousand illustrations, for the most part excellently reproduced from clinical photographs, but there are also many diagrams explaining various points of technique, which will be found most useful. The whole volume is excellently got up, and, considering the amount of matter contained in it, remains moderate in size and easy to handle. We commend it with confidence both to general practitioners and to specialists.

Octavo volume of 1,095 pages, with 933 illustrations. By GEORGE C. ANDREWS, M.D., Associate Professor of Dermatology, College of Physicians and Surgeons (Columbia University), New York City. Cloth, 55s. net.

BOGERT'S NUTRITION and PHYSICAL FITNESS *NEW*

The modern physiological conception of nutrition is stressed throughout this book. This practical teaching approach brings home clearly to the student how his new knowledge can serve as a tool for building positive health. Dr. Bogert interestingly acquaints the student with the classification of foods, the nutritional requirements of the body, body processes, meal planning and preparation, diet for children, for adults, in pregnancy, constipation, obesity, malnutrition, and other conditions in which diet is of importance.

12mo of 554 pages, illustrated. By L. JEAN BOGERT, Ph.D., formerly Instructor in Medicine, University of Chicago. Cloth, 14s. net.

BUIE on HAEMORRHOIDS *NEW*

In this *new Mayo Clinic Monograph* Dr. Buie presents the direct examination of the anus, rectum, and sigmoid; gives the treatment of haemorrhoids, with particular emphasis on the *injection treatment*, and gives a *treatment of anal pruritus* which he has been successfully using for a number of years. Dr. William J. Mayo has written the Foreword.

Octavo of 178 pages, illustrated. By LOUIS A. BUIE, M.D., Section on Proctology, The Mayo Clinic, Rochester, Minn., and Associate Professor of Surgery, The Mayo Foundation, University of Minnesota. Cloth, 16s. net.

ROWNTREE & SNELL on ADDISON'S DISEASE *NEW*

Drs. Rowntree and Snell present in this *new Mayo Clinic Monograph* an analysis of 108 cases of Addison's Disease which came to the Mayo Clinic. Clinical investigations at the bedside have been supplemented by observations made from time to time as the patients returned for re-examination or for modification of treatment. The *Swingle and Pfiffner* cortical hormone treatment is here detailed as well as the *Muirhead treatment*. The Foreword is by Dr. Charles H. Mayo.

12mo of 325 pages, illustrated. By LEONARD G. ROWNTREE, M.D., and ALBERT M. SNELL, M.D., Division of Medicine, The Mayo Clinic and The Mayo Foundation, Rochester, Minn. Cloth, 18s. net.

JORDAN'S GENERAL BACTERIOLOGY *NEW (10th) EDITION*

The new (10th) edition of Jordan's "Bacteriology" has been issued after one of the most thorough revisions this book has ever had. The heaviest revision has been given to the sections on variations, undulant fever, paratyphoid group, filterable virus diseases, pathologic yeasts, and anaerobes. The bacteriophage problem has been treated in greater detail. The question of nomenclature has been dealt with, rather with the thought of convenience than the strict rules of taxonomy. Changes of less major character have been made throughout the entire book, bringing the work into accord with the very latest knowledge of the rapidly-changing subject of Bacteriology. It is one of the finest books in all bacteriological literature.

"Maintains its position as one of the best balanced and most scholarly of the current textbooks upon bacteriology and has the additional charm of viewing the subject widely, not being slavishly devoted to the pathogenic micro-organisms to the exclusion of due consideration of other forms."—THE LANCET.

Octavo volume of 819 pages, illustrated. By EDWIN O. JORDAN, Ph.D., Professor of Bacteriology at the University of Chicago and at Rush Medical College. Cloth, 22s. net.

INDEX OF TREATMENT

A Complete Guide to Treatment in a form convenient for reference.

Edited by ROBERT HUTCHISON, M.D., F.R.C.P.,

Physician to the London Hospital, and to the Hospital for Sick Children, Great Ormond Street, London.

In conjunction with 90 Representative Authors.

FROM PRESS NOTICES OF FORMER EDITIONS:—

"We cannot do more than recommend it in terms of high laudation; it is a volume that should be in the hands of every practitioner of medicine."—*British Medical Journal.*

"Since we first reviewed this book on its appearance in 1908 seven further editions have been issued—a gratifying evidence of success which establishes it beyond the reach of criticism. Its general plan and high standard of excellence are doubtless well known to our readers."—*Lancet.*

"This index is well worthy of its success, reflecting as it does the latest teaching in medical science."—*Medical Press and Circular.*

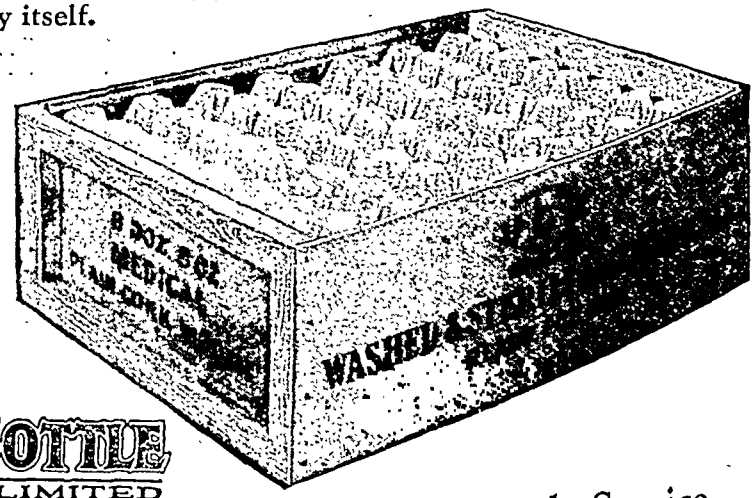
THE CAR WITH THE TWO YEARS GUARANTEE



Everything to look for on a Bottle..

IMITATION may be the sincerest form of flattery, but the extent to which the U.G.B. Medical Bottle is imitated in inferior quality is far from gratifying.

Designed some ten years ago as an ideal dispensing bottle, it is now the standard for this purpose. The consistently high quality, accurate capacity and attractive appearance, places the U.G.B. Medical in a class by itself.

The success of this bottle has been greatly enhanced by the introduction of the "WASHED & STERILIZED READY-TO-USE BOTTLE" packed in non-returnable Dustproof Solid Fibre Cartons—supplied either for Corks or complete with Rustless White Enamelled Screw Caps.

Obtainable from all leading Wholesalers.

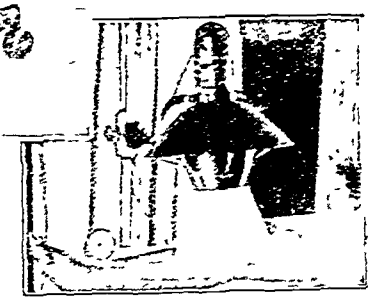
One unit *for* three tasks

General Ultra-Violet irradiation with the Alpine Sun Lamp.

The new Hanovia Duo-Therapy Unit giving three forms of light treatment.

(BRITISH MADE)

AMONG those physicians now using Hanovia Lamps, many an enthusiast was at first sceptical whether his practice gave scope for actinotherapy. It is common experience that the real benefits of light treatment become self-evident in use, both to the practitioner and his patients. Why not investigate for yourself the very complete data which we offer to the profession alone?



At this date you have the advantage of modern apparatus far in advance of previous types. It is easier in manipulation, quicker and more effective in results. The Duo-Therapy unit incorporates standard lamps of full power for three forms of light treatment, i.e.:—

General Ultra-violet Radiation with the famous Alpine Sun Lamp in a new, intensified, improved model.

Local Luminous Heat Therapy for acute and painful conditions, with the Modified Sollux Lamp.

Conjoint treatment with both lamps, facilitated by their assembly in one unit with independent controls.

Use the Coupon.

STANIFORM

Regd. BRAND. Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is contra-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A panacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are two recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"After using 'Staniform' Ointment in cases of Impetigo and other septic conditions of the skin, I was much impressed by the rapid response to treatment. Also herpes on the lip quickly disappeared after application of 'Staniform' Ointment."

"Festering wound on left heel—when first seen was about the size of a shilling, with a good deal of pus. Foot much swollen—dressed with 'Staniform' Ointment—healed splendidly in four days."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments.

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing."

STANIFORM LTD., CARNWATH ROAD, LONDON, S.W.6

A SIMPLE ANALGESIC

The popular belief in the value of external applications for the easing of pain and the lessening of congestion is as well founded as it is universal. There are few illnesses in which, at some stage or other, THERMOGENE brand of Medicated Wadding fails to give relief and comfort. It acts as a mild yet potent stimulant of the local circulation, reducing congestion due to toxic irritation by bringing about a freer flow of blood through the vessels adjacent to the congested area. It is simple to apply, cleanly in removal, easy of graduation, and harmless yet effective.

THERMOGENE brand of Medicated Wadding is a carefully prepared pure cotton wadding, remarkably soft and fleecy, freed from dust and other impurities, and impregnated with skin-stimulating vegetable essences.

Rapid gain in weight

is secured in cases of retarded development by the use of

Mellin's Food

because it supplies Malto-Dextrin, the most readily absorbed of all carbohydrates.

It contains peptised vegetable proteins and essential amino-acids, which, by lowering the pH of the mixture, ensures complete fat emulsification and casein flocculation.

Thus gastric and intestinal irritations are allayed and normal conditions quickly restored.

Samples and booklet containing full details of composition and calorific value of mixtures suggested for different ages and conditions, post free, from:—MELLIN'S FOOD LTD., Dept. G/51, London, S.E.15.

IN HÆMORRHOIDS

The Mental Effect

ANUSOL

EVEN though there is no acute pain, merely a sensation of discomfort, mental depression is a commonly observed symptom in hæmorrhoids. Constipation gives a feeling of weight as if the rectum were not properly emptied.

Anusol Brand Hæmorrhoidal Suppositories, by their decongestive action and emollient effect, give early relief from pressure symptoms. In most instances painless evacuation occurs soon after introducing the suppository, because the contents of the rectum are softened.

As the symptoms improve, mental depression disappears.

Nothing gives such impressive reassurance to the patient as prompt treatment and early relief. This he will obtain if treatment is begun at the doctor's consulting room. Let us send you a trial supply for use immediately after examination.

REINFORCED COD LIVER OIL

—BOOTS—

THE therapeutic value of Cod Liver Oil is fully appreciated by the medical profession. It is recognised for its specific action (due to its high content of Vitamins A and D) in Rickets, Affections of the Chest, and diseases arising out of Malnutrition. Reinforced Cod Liver Oil—Boots is a biologically controlled preparation containing five times the normal amount of Vitamin D in addition to the normal amount of Vitamin A. The advantage of a concentrated oil needing only a fifth of the usual dose will be appreciated. Four fluid ounces of Reinforced Cod Liver Oil—Boots, contain the same amount of Vitamin D as one pint of the finest Norwegian oil.

In 4-oz. bottles, 2/6

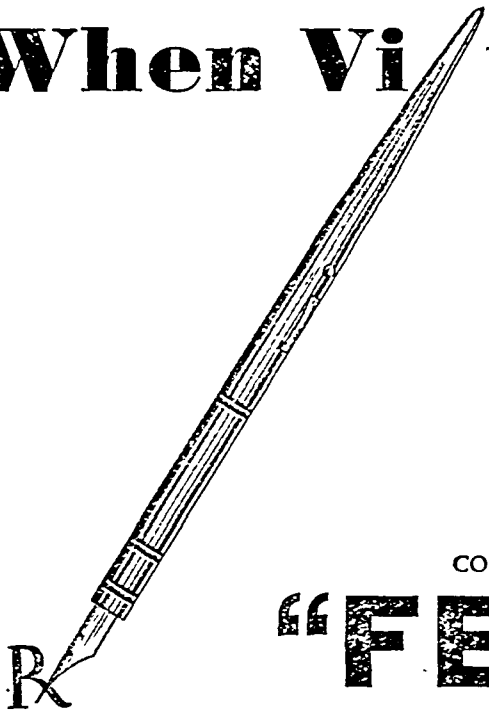
IDOZAN HAS BEEN REGULARLY PRESCRIBED BY DOCTORS IN FIFTEEN DIFFERENT COUNTRIES

Effective Ferrotherapy

IDOZAN IS A COLLOIDAL IRON SOLUTION, NEUTRAL, AND CONTAINING 5 PER CENT. OF PURE IRON (Fe).

One teaspoonful of IDOZAN contains 25 ctgrms. of pure iron (Fe).
One dessertspoonful of IDOZAN contains 50 ctgrms. of pure iron (Fe).
One tablespoonful of IDOZAN contains 75 ctgrms. of pure iron (Fe).



Thus, by means of relatively small doses of IDOZAN it is possible—without any inconvenience to the patient—to give much larger doses of iron than could be accomplished with many of the older preparations. In cases of severe anaemia, for instance, one may very well give the patient one tablespoonful of IDOZAN three times daily. This dosage means a daily intake of 2.25 grams of pure iron.

Packings—8-oz. & 40-oz. bottles.

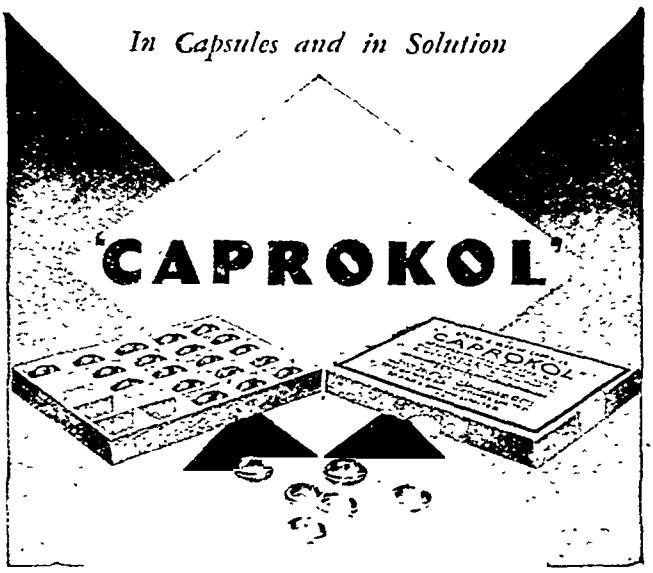
MONSOL

BRAND

Liquid GERMICIDE *in all*

MATERNITY WORK



Samples for clinical trial gladly sent to members of the Medical Profession by the manufacturers.

The majority of cases of Puerperal Sepsis can be attributed to the introduction of Streptococci from without during labour, when the bodily defences are weakened. This cause of infection is preventable by the use of an efficient and safe germicide.

- MONSOL IS EFFICIENT.—(1) Because it has a selective action on Streptococci. (2) Because its action is unimpaired by the presence of organic matter such as blood and serum.
- MONSOL IS SAFE because it is so bland in action that it can be used at a dilution many times stronger than that necessary to destroy Streptococci, without any risk of irritating even delicate mucous membranes
- It appeals to both Doctor and Nurse because even after prolonged use it never irritates or roughens the hands.

EDINBURGH & LONDON (155/7, Farringdon Road, E.C.1).

Produces 1½-times as much energy and is more digestible

Tests carried out at a famous Research Institute prove the superiority of this wheat cereal over oatmeal

The graph above illustrates the greater digestibility and energy value of wheat, as opposed to oats. Tests showed that after 4 hours the digestion of oatmeal was almost at a standstill, while that of "Cream of Wheat" continued at a scarcely diminished level for another 4 hours. When digestion was complete, the sugar yield from "Cream of Wheat" was 50% greater, and productive therefore of 1½-times as much energy.

The superiority of "Cream of Wheat" over oatmeal as a first starch food for infants has been conclusively proved by a series of experiments recently conducted in the laboratories of a leading biochemical Institute.

"Cream of Wheat" prominent on the diet sheets of leading British pediatrists

Made from the granulated endosperm of the best hard wheat, "Cream of Wheat" contains 72 per cent starch, the importance of which in the feeding of infants is now generally recognized. "Cream of Wheat"—with this high starch content, its energy output, and its amazing ease of assimilation—is prominent on the diet sheets of leading British pediatrists.

No outside husk of the wheat grain is used in the manufacture of "Cream of Wheat," consequently there is nothing in this product to cause irritation to the intestinal tract. It can be given with assurance, not only to infants from the weaning stage, but also to adults during the post-operation period and convalescence. A professional card will bring you fuller details of the above tests, and a sample of this cereal. Dept. W.12, Fassett & Johnson Ltd., 86, Clerkenwell Road, London, E.C.1.

"CREAM of WHEAT"

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidol Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative. "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

Alasil

THE NATURAL MINERAL WATERS
OF
CARLSBAD
Sprudel, Muhlbrunnen, and Schlossbrunnen

These waters act:

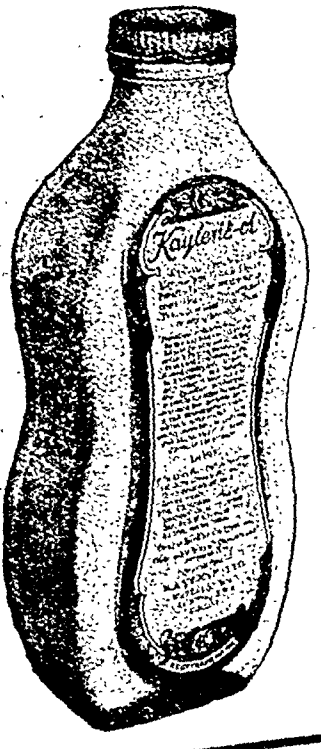
(1) By immediate contact with the mucous membrane of the stomach and alimentary canal, allaying pains and spasms in these organs, and stimulating the digestive organs into activity.

(2) Through the blood. That is, they change its condition by increasing the proportion of alkali in the blood as well as in all derivative secretions (gall, urine, etc.).

Largely prescribed in cases of

Chronic Gastric Catarrh, Hyperaemia of the Liver, Diabetes, Gout, Gall-stones, Renal Calculi, Diseases of the Spleen, and of the Kidney and Urinary organs.

Bottled under Official Supervision at Carlsbad and regularly imported by the Sole Agents:



INGRAM & ROYLE, Ltd.,

BANGOR WHARF, 45, BELVEDERE ROAD, LONDON, S.E.1.

And at LIVERPOOL and BRISTOL.

Samples and Descriptive Pamphlet forwarded on application.

DETOXICATE WITH KAYLENE-OL

Since the introduction of Kaylene-ol, the adsorption treatment of putrefactive toxaemias has received increasing attention, and to-day this method of detoxicating the contents of the bowel is recognised as a valuable addition to the medical treatment of gastro-intestinal disorders.

Samples and "Adsorption" Literature obtainable from the Manufacturers.

HEWLETT'S
ORIGINAL PREPARATIONS.

HORMONIGEN
(HEWLETT'S)

Hormonigen Tablets (Hewlett's) contain the hormones of the thyroid, pituitary, ovary, and testes

Useful in Neurasthenia and all asthenic conditions, obesity, chronic cardiac cases, aplasias of the pluriglandular system, and in anæmia In Amenorrhœa, Dysmenorrhœa, and at the Menopause, Hormonigen is particularly effective, and even in chlorosis

If there is high blood pressure, Hormonigen Sine Pituitary is indicated

PRICE HORMONIGEN, OR HORMONIGEN SINE PITUITARY,

3/3 PER 100; 30/- PER 1,000.

UNG. IODERMIOL

An ointment of IODERMIOL that contains about 5 per cent of Iodine, and is, therefore, stronger than the B P Ointment, whilst it does not harden or discolour the skin

It has been found most useful for Enlarged Glands, Rheumatic and Gouty Affections, Lumbago, Sciatica, Swollen and Stiff Joints, Skin Diseases, Ringworm, etc Ung Iodermiol has also been used in cases of burns and scalds, and in the treatment of Chronic Lymphadenitis, Simple Bronchocele, and Atrophic Rhinitis, and in Purulent Ulcerative Otitis

PRICE 6/- PER LB.

UNGUENTUM IODERMIOL et METHYL SALICYL. (HEWLETT'S)

Useful in the treatment of Enlarged Joints, Synovitis, Rheumatoid Affections, etc.

PRICE 7/6 PER LB.

LIN. BETULÆ CO.
(HEWLETT'S)

Therapeutically equivalent to several times its weight of Sodium Salicylate without causing headache, tinnitus, etc. Has proved most useful in the external treatment of pure Rheumatism, Sciatica, Lumbago, etc. The external dose is about one drachm rubbed over the affected parts.

In 5, 10, 22, 40, and 90-oz Bottles.

PRICE 10/6 PER LB.

VERONIGEN
(HEWLETT'S)

A liquid Preparation of this prompt and reliable HYPNOTIC has long been desired as a useful means of procuring sleep When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, and in ordinary cases of insomnia one fluid drachm of Veronigen (Hewlett's) is quite sufficient dose for an adult.

Dose for Adults.—One fluid drachm diluted, about one hour before going to bed

For Nervous Sleeplessness in Children.—10 to 20 minims diluted

VERONIGEN, 10/6 PER LB.

MIST. PRUNI VIRG. CONC.
(HEWLETT'S)

A valuable stimulant and expectorant cough mixture, containing Carbonate of Ammonium, Ipecacuanha, Senega, Squill, and Syrup of Wild Cherry Bark. Quite free from Morphine, Opium, or poisons, so can be safely administered to children.

Dose: 1 to 2 drachms diluted.

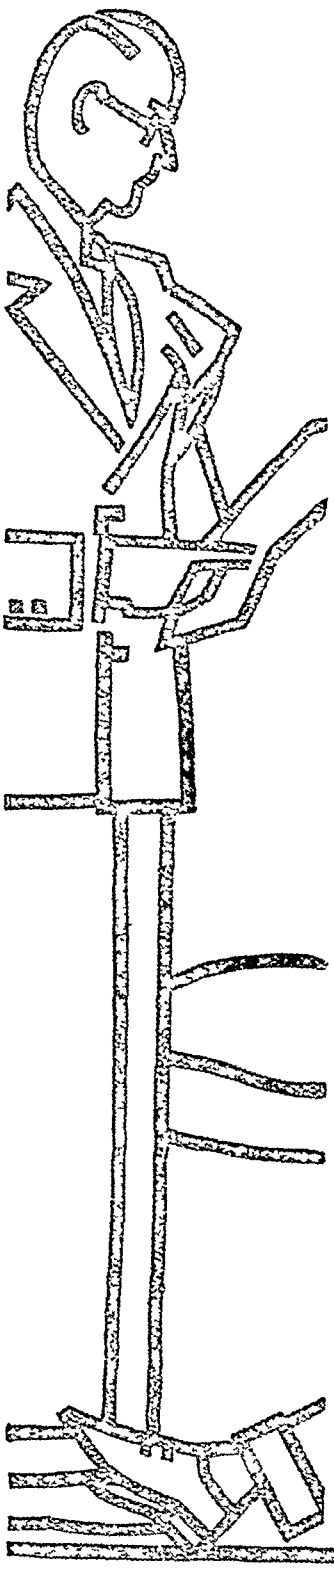
In 22, 40, and 90-oz. Bottles only.

PRICE 3/3 PER LB.

MIST. TUSSI RUB. CONC.
(HEWLETT'S)

A favourite and economical cough mixture, containing Hydrobromic Acid, Chlorodyne, Dilute Hydrocyanic Acid, etc. Most successful in allaying post-influenza coughs that are so persistent. One or two ounces diluted with water to make eight ounces forms one of the most effective and elegant mixtures that can be made, and certainly the least expensive.

In 22-oz., 40-oz , 4½-lb , and 8-lb Bottles only.



PRICE 2 9 PER LB.

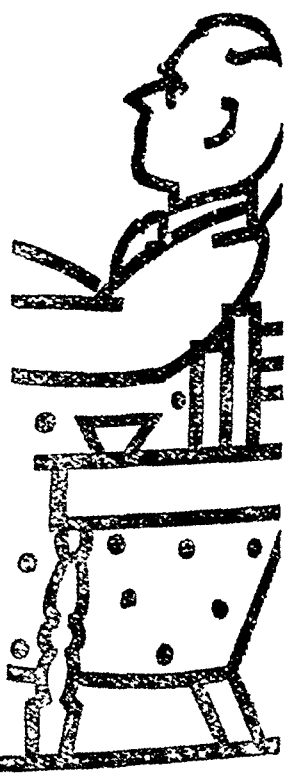
when you forbid a patient caffein please hasten to add—

When a patient's face falls at your order to avoid caffein, please hasten to add a word of cheer.

Console the patient with the fact that, in forbidding caffein, you are not forbidding the satisfying flavour of coffee. Remind the patient that he can still drink H.A.G. Coffee—genuine, delicious coffee with the effects of caffein minimized.



There is, however, another reason besides your own benevolence for recommending H.A.G. Coffee. By letting your patient enjoy the rich and satisfying flavour of H.A.G. Coffee, you remove all temptation to drink caffein-containing coffee on the sly.

Rich in flavour—tempting in aroma

H.A.G. Coffee is real coffee—a superior blend of the choicest Central and South American coffees. The decaffeination process takes place *before* the coffee beans are roasted. This leaves intact all the mellow flavour and fragrance that make coffee "the beloved beverage." Coffee experts recognise that no other blend is finer.

H.A.G. Coffee is under the Independent Control of The Institute of Hygiene and British Analytical Control.

Your grocer stocks H.A.G. Coffee—ground or in the bean and in vacuum tins that preserve its freshness and its fragrance. Or send the coupon below for a liberal sample tin of H.A.G. Coffee. With it we shall be pleased to send a copy of "Coffee drinking in its relation to Health," a more complete discussion of H.A.G. Coffee. Send the coupon now.

Remarks on ENDOMETRIOSIS AND ENDOMETRIOMATA*

BY

DANIEL DOUGAL, *M.C.*, M.D., F.C.O.G.

PROFESSOR OF OBSTETRICS AND GYNAECOLOGY IN THE UNIVERSITY OF MANCHESTER; HONORARY SURGEON TO THE ST. MARY'S HOSPITALS; LATE HUNTERIAN, AND HONORARY ASSISTANT GYNAECOLOGICAL SURGEON TO THE MANCHESTER ROYAL INFIRMARY

It is just ten years since J. A. Sampson read his epoch making paper on perforating haemorrhagic cysts of the ovary,[1] and a sufficient interval has now elapsed to enable us to take stock of the position and assign these endometriomatous tumours to their proper place in gynaecological pathology and practice. This is easier to-day, because the novelty and glamour surrounding these tumours has largely disappeared, and the more adventurous spirits in gynaecology are turning their attention to other problems. I cannot pretend to discuss the subject adequately in the time at my disposal, but will endeavour to place before you the principal biological, pathological, and clinical features, reinforcing them as far as I can by statistics from a series of 137 cases operated on by myself during the past five years.

By endometriosis is meant the pathological state brought about when fragments of endometrium leave their proper situation in the uterus and implant themselves in neighbouring tissues, and by endometriomata the tumours which develop if conditions are favourable for the growth of these implants. In my opinion the vast majority of endometriomata arise in this way, but possibly a small number may be derived from Müllerian rests.

An endometrioma is therefore a tumour containing endometrial elements, or, at any rate, elements which look and behave like endometrium. Gland tubules in a richly cellular stroma are the histological criteria, but there may also be present a variable quantity of effused blood, cystic spaces lined by columnar or flattened epithelium and containing tarry blood, or hyperplasia of the muscular or fibrous tissue of the organs invaded. Physiologically these endometrial elements betray their origin by passing through the various phases of the menstrual cycle, including that of menstrual haemorrhage, and by undergoing a decidual change during pregnancy, though the latter, of course, is not specific to endometrium, but found constantly in the ovaries, and frequently in the peritoneal covering of the other pelvic organs.

Etiology of Endometriosis

In 1908 Cullen[2] examined a number of specimens of diffuse endometrioma of the uterus, or diffuse adenomyoma as it was then called, and found as a result of his investigations that in places there was direct continuity between the endometrium proper and that contained within the tumour and frequently an actual communication between the uterine cavity and several of the cystic spaces in the growth. This became known as the diverticular theory, and may be regarded as the simplest form of endometriosis. In certain other uterine endometriomata no such continuity can be demonstrated, and in these it must be assumed that the misplaced endometrium has reached its new situation by metastasis through the lymph vessels or venous channels of the uterine wall. Similar tumours not infrequently follow tuberculosis of the uterus or tubes, so it is possible that an inflammatory process may be a factor of some importance.

Many theories were advanced to explain the occurrence of extrauterine endometriomata, different authorities suggesting that they were derived from Wolffian or Müllerian rests or by metaplasia from the peritoneal endothelium. In 1921, however, Sampson illuminated the whole problem with his theory of retrograde menstruation and cellular spill. According to this theory, some of the menstrual discharge with its normal content of endometrial fragments may pass backwards through the Fallopian tubes and so reach the pelvic cavity. The structures lying in closest relationship to the fimbriated ends of the tubes naturally receive most of the fragments, or implants as they are now called, but gravity and the normal movements of bowel and bladder render a much wider dissemination possible.

That retrograde menstruation is more than a mere theory, and does actually occur, is within the experience of every gynaecological surgeon; as when performing abdominal operations during the menstrual period he must have occasionally observed blood dripping from the fimbriated ends of the tubes or lying in the posterior cul de sac. Parity, retroversion of the uterus, enlargement or distortion of the uterine cavity by fibroids, or any obstruction to the flow of menstrual blood through the cervix, may all predispose to this retrograde flow. Direct endometriosis of the peritoneal cavity through the uterine wall may of course follow such operations as involve incision or puncture of the uterine wall—Caesarean section, or myomectomy, for instance. In my own series of cases, previous operations included 10 per cent. of curettings, 1 Caesarean section, 3 operations upon the appendages, and 7 appendicectomies.

However brought about, the result is a shower of implants which reaches the pelvic cavity and the various organs lying within it. The subsequent fate of these implants then depends on several factors—among others, their vitality and virulence, and the nature and resisting powers of the tissue invaded. The ovary and recto-vaginal septum appear to offer the best conditions for active proliferation, and it is therefore in these situations that extrauterine endometriomata are most commonly found. Three possible explanations in the case of the ovary may be the absence of a peritoneal covering, the breach of surface continuity which follows ovulation, and the greater concentration (possibly) in the ovary of the specific hormones controlling menstruation. There is always a definite reaction on the part of the invaded structures, and this leads to adhesions of great density and to hyperplasia of any fibrous or muscular tissue which may be present in the vicinity. The menstrual products of the tumour itself are also peculiarly irritating and still further intensify the local reaction.

From its very nature, endometriosis must result in a wide distribution of endometrial elements, and this is particularly so when it has followed retrograde menstruation and cellular spill. Even in the case of direct invasion of the uterine wall from the cavity it is quite possible that the resulting diffuse tumour really represents a number of different implants, each of which is surrounded by hyperplastic fibro-muscular tissue. The usual result of endometriosis, therefore, is the formation of multiple tumours in the pelvic organs, though not all of these become sufficiently prominent to form part of the clinical picture.

Pathology of Endometriosis

The various elements composing endometrial tumours have already been referred to, and it is only necessary at this stage to describe the naked-eye appearances of pelvic endometriosis and the various fully developed tumours which may arise from that condition. Endo-

* Paper read to the Section of Obstetrics at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

metriosis following direct invasion of the uterine wall from the endometrium usually results in a diffuse tumour, largely made up of hyperplastic fibro-muscular tissue, but also containing numerous islets of misplaced endometrium, some of which have become cystic and filled with blood. The external contour of the uterus is not usually altered, as the enlargement is uniform. The tumour differs from a fibroid in possessing no capsule, and in having its cut surface studded with the endometrial areas already referred to. Like a fibroid, however, it may occasionally grow outwards or inwards, and become pedunculated subserous, or submucous, as the case may be. In cornual tumours there is a localized swelling near the inner end of the tube, and on section this is frequently found to contain a cyst filled with tarry blood.

Endometriosis following retrograde menstruation and cellular spill produces naked-eye appearances which are unmistakable. The fimbriated extremities of the Fallopian tubes are usually patent. Dotted about the pelvic peritoneal cavity are numerous purplish blebs which microscopical examination will demonstrate to be endometrial implants. Some of these have irritated the peritoneal surfaces and led to dense adhesions, as evidenced by fixation of the ovaries and tucking up of the utero-vesical or utero-rectal peritoneum.

If conditions are favourable for further growth, definite endometriomata are produced ; these differ in their naked-eye appearances according to the particular organ affected. In the ovary the physiological activity of the implants as judged by the amount of blood effused during menstruation is most marked, and the tumour therefore becomes cystic and filled with tarry blood. Sampson, indeed, regards the ovary as "a sort of intermediate host, hotbed, or incubator, which may impart greater virulence to the tumour elements, and, if subsequent rupture occurs, [illegible] tumour [illegible] times much [illegible] to a wider distribution of the neoplasm." The [illegible] of a large unilo[illegible] usually about the size of a walnut, but sometimes larger, and may even reach the dimensions point of implanta[illegible] always escape when the [illegible]dar cyst. It is adherent at the original The firm walls of the cyst the[illegible] and, consequently, its contents and the point of rupture remain[illegible]ry is separated at operation. addition to the primary adhesion, [illegible] prevent complete collapse, present, and these firmly attach the ova[illegible]ers are usually structures, and, when separated, expose a raw [illegible] adjacent surface. These adhesions probably result from leaka[illegible] [illegible]nular the irritating cyst contents. [illegible] of

Next in importance comes the tumour of the recto-[illegible] vaginal space, which develops presumably from an implant [illegible] in the pouch of Douglas. The appearances are aga[illegible] characteristic, the rectum being tucked up and adhe[illegible] to the posterior surface of the uterus and its wall [illegible] thickened and nodular, sometimes to such a degr[illegible] it closely simulates a malignant tumour. The gro[illegible] also involve the cervix and posterior vagina[illegible] even project as nodules or polypi into t[illegible] vaginal fornix.

The uterine wall itself may develo[illegible] as the result of endometriosis of t[illegible] implants attaching themselves primar[illegible] surface of the uterus or invading it fr[illegible] established in the ovary, recto-vaginal [illegible] The direct[illegible] of growth is towards t[illegible] however, and not away from it, as in th[illegible] already described.

Similar tumours are not infrequently f[illegible] Fallopian tube, round or utero-sacral ligam[illegible] colon, small intestine, and more rarely as p[illegible] curiosities in the appendix, umbilicus, inguinal [illegible] scar of a previous abdominal operation.

DOSAGE

In my own series the distribution of the principal tumours was as follows:

Diffuse uterine	6 cases
Cornual	6 cases
Ovarian	44 cases
Recto-vaginal	44 cases
Ovarian and recto-vaginal	34 cases

The ovarian and recto-vaginal tumours, in addition to being frequently present together in the same case, were often associated with similar growths in the utero-sacral ligaments, uterus, or bowel ; but separate classification of these is unnecessary, as all are essentially part of the same process.

The question of other lesions associated with endometrioma is important, and, of these, uterine fibroids must take first place. They were present in 40 per cent. of my own cases, and of sufficient size to be of clinical importance in 27 per cent. Looking at it from the opposite point of view, 10 per cent. of all fibroids operated on during the five years covered by the series were associated with endometrioma. Their influence as a possible factor in retrograde menstruation has already been mentioned, and would be expected to be more apparent in the case of single or nulliparous women. In single women the percentage of fibroids was actually about 50. Sampson has advanced a theory that fibroids may actually originate in endometriomata of the uterine wall, the endometrial elements disappearing at a later stage, and leaving only the fibromyomatous stroma.

True pelvic inflammation may be associated with endometriosis, but is unlikely to have advanced to the stage of tubal occlusion, as retrograde menstruation would then be impossible. Curtis[3] believes that the two conditions are actually antagonistic, having noticed that, with improved prophylaxis in the management of gonorrhoeal infection and the resultant decrease in the incidence of salpingitis, there has been an enormous increase in the number of patients with misplaced endometrial tissue.

There appears to be no relationship between endometrioma and carcinoma of the uterus, but in two of my cases there was an associated malignant growth of the cervix. With ovarian carcinoma it is otherwise, however, and Sampson,[4] after examining a number of specimens, has come to the conclusion that malignant ovarian disease may develop in misplaced endometrial tissue.

Clinical Features of Endometrioma

Endometriosis is possible at any age between puberty and the menopause, but treatment of the resulting endometriomata is usually carried out during the period of sexual maturity. In my own cases 91 per cent. were operated on between the ages of 30 and 50 years. Twelve patients were under 30 years and nine over 50. The tumours are found most commonly in married women, there were only 17 single women among my 137 cases of endometrioma.

It is not possible to give statistics as to the frequency of endometriosis, but the number of endometriomata producing symptoms is considerable. I operate on between twenty-five and thirty of these cases each year, the laparotomies amounting to about 11 per cent. of the total abdominal operations. This figure is not very different from that given by Sampson, which is 12 per cent. of abdominal operations carried out during sexual maturity.

In its early stages, endometriosis produces few symptoms for which it can be held responsible, and may only be discovered accidentally when the abdomen is opened for some other condition. As the implants mature and adhesions form, however, there will usually be increasing pelvic discomfort, dysmenorrhoea, and disturbances of the menstrual flow. Even then, certain associated pathological

such as fibroids or malignant disease may dominate the clinical picture and produce the symptoms for which the patient actually seeks advice. After consideration of my own cases, I came to the conclusion that endometrioma was entirely responsible for the symptoms in 65 per cent., and partly responsible in 8.7 per cent., while fibroids were entirely responsible in 21 per cent.

Coming to the question of symptoms it must be stated at the outset that there is not one which will definitely point to the existence of endometrioma. Lower abdominal pain is very common, and in my series was present in 40 per cent. of cases. Dysmenorrhoea, particularly of recent origin, is probably the most characteristic symptom, but it is by no means constant, and was complained of in only 31 per cent. of cases. When present, it is presumably due either to pre-menstrual congestion of the endometrial elements or to tension following accumulation of menstrual blood. Menorrhagia or epimenorrhagia is another common symptom, and was also found in 31 per cent. It has been suggested that this symptom is more likely to be due to associated fibroids than to endometrioma, but this is not borne out by my own figures, as the percentage of fibroids in patients complaining of this symptom was very little higher than that for the whole series—47 as against 40. Bearing down and rectal discomfort are frequently met with when the growths are in the recto-vaginal space, or when there are adhesions in the neighbourhood of the rectal wall. Backache is such a common complaint in women that its value in differential diagnosis is strictly limited, but this symptom is prominent when the ovaries are adherent in the pouch of Douglas or when the rectum or back of the cervix is involved. Dyspareunia is frequently complained of in similar circumstances, also shooting or "electric" pains extending down into the uterus and vagina. Occasionally there may be pain down one or other leg when an ovarian endometrioma is adherent to the pelvic wall. Marked constipation may be associated with extensive involvement of the rectum or other parts of the alimentary tract, and a blood-stained discharge present when a recto-vaginal growth has perforated the vaginal wall.

The physical signs naturally depend on the situation of the tumour. In the ordinary diffuse uterine tumour there will usually be moderate and uniform enlargement of the uterus, but with cornual tumours there may be definite irregularity. In either case the physical signs will closely resemble those of a uterine fibroid, and differential diagnosis will be impossible unless increasingly severe dysmenorrhoea has led one to suspect the true state of affairs.

In ovarian endometrioma there will be an enlargement and fixation of one or both ovaries, and as these are usually adherent to the back of the uterus, the latter will be retroposed and its mobility lessened. In the absence of evidence pointing to pelvic infection, such a finding should lead one to suspect an endometrial tumour. When the growth is in the recto-vaginal space, the physical signs are most characteristic, the infiltrating character of the tumour and the presence of tender shotty nodules in the wall of the posterior fornix being sufficient evidence upon which to base a diagnosis. Recto-vaginal examination will prove helpful in these cases, as it may reveal fixation of the rectum to the back of the tumour.

To sum up, it may be stated that there are no pathognomonic symptoms of endometrioma, but that increasing dysmenorrhoea, menorrhagia, and dyspareunia should lead one to suspect the condition. The physical signs, however, are more characteristic, at any rate in the case of extrauterine growths, and fixation of the uterus and ovaries associated with a shotty nodular tumour behind the cervix affords conclusive evidence.

Endometriomata and the Reproductive Function

That endometriomata seriously interfere with childbearing is shown by the fact that patients with these tumours usually give a history of sterility or of no births having occurred for several years. In my series of 137 cases, after excluding 17 single women and 8 women who had been married less than three years, 41 per cent. were sterile. Of the parous women 75 per cent. had not been pregnant for at least five years and 50 per cent. for at least ten years. There was no special incidence of abortion, the abortion/full-term ratio being 1 to 5.8. Associated fibroids may be partly responsible for the absolute or relative sterility met with in those cases, but that their influence is not very great is shown by the fact that there is little difference in the incidence of these tumours in nulliparous and parous women, the percentages being 46 and 41 respectively. Endometrioma, at any rate in its early stages, is not an absolute bar to pregnancy, and I certainly know of one patient with a well-marked endometrioma of the recto-vaginal space who subsequently became pregnant, although no actual treatment was carried out for the tumour itself.

Treatment

As endometriomata are usually widely distributed and of an infiltrating character, it will be understood that conservative measures are only possible in the early stages, and that even then the chances of recurrence are considerable. A conservative policy is only justifiable, however, if one ovary alone is involved, or if there are isolated nodules in the recto-vaginal space causing dyspareunia.

In my own series I find that the uterus and all ovarian tissue were removed in 83 per cent. of cases, the operations on the remainder consisting of excision of one ovary or of nodules in the recto-vaginal space. I have no experience of radium in the treatment of endometrioma, but I would prefer local excision in early cases as being less likely to interfere with ovarian function. Owing to the dense adhesions present and the frequent involvement of bowel, radical operations may be among the most difficult in gynaecology, but the results both immediate and remote are extremely good. Total is preferable to subtotal hysterectomy, and it is quite unnecessary to excise infiltrating growths in the rectum or other parts of the alimentary tract, as atrophy will follow if both ovaries are removed.

There was only one death in the series, representing an operative mortality for the radical operations of 0.8 per cent. One of the patients treated by removal of the affected ovary has since been delivered of two full-term children. This is my only experience of pregnancy following conservative surgical treatment of endometrioma.

Summary

1. Endometriosis is defined as the pathological state brought about when endometrial fragments invade the uterine wall or, passing through the Fallopian tubes in regurgitant menstrual blood, reach the pelvic cavity and the structures within it.

2. Cullen's diverticular and Sampson's retrograde menstruation and cellular spill theories are therefore accepted as providing the most reasonable explanation of uterine and extrauterine endometriosis respectively.

3. Endometrioma is defined as one of the tumours which develop when misplaced endometrial fragments or implants proliferate sufficiently to form clinico-pathological entities, and is accepted as the most suitable term to apply to all such tumours, whether uterine or extrauterine.

4. The clinico-pathological features of endometrioma are described, and stress is laid on the multiple character of the lesions resulting from endometriosis.

5. Surgical treatment is discussed, and radical measures are advocated for all but the earliest cases.

6. Statistics are quoted from a personal series of 137 cases operated on during the last five years, and individual cases referred to where necessary.

JAUNDICE IN CHILDHOOD*

BY

A. C. HAMPSON, *M.C.*, M.A., M.D., M.R.C.P.

ASSISTANT PHYSICIAN AND ASSISTANT PHYSICIAN IN THE CHILDREN'S DEPARTMENT, GUY'S HOSPITAL; PHYSICIAN TO THE DREADNOUGHT HOSPITAL AND QUEEN MARY'S HOSPITAL, STRATFORD

Although, strictly speaking, the term "jaundice" implies staining of the skin, mucous membranes, or conjunctivae, such general staining by bile-pigments is always associated with an excess of bilirubin in the blood; and as such excess is the most constant finding, and precedes the staining of the tissues, it is convenient to regard excess of bilirubin in the blood as the measure of the condition under discussion. Before dealing with the various conditions, which in children are characterized by jaundice, it is useful briefly to review the mechanism of its production.

The modern view, well supported by experimental and clinical evidence, suggests that bilirubin is formed from haemoglobin by the cells of the reticulo-endothelial system, chiefly by those of the spleen, liver and bone-marrow. The bilirubin so formed is further changed by the polygonal cells of the liver and excreted through the bile-channels into the alimentary tract. The two forms of bilirubin are not physio-chemically identical, and can be distinguished by the test devised by Hijmans van den Bergh.[1] The bilirubin produced by the action of the endothelial cells gives an "indirect reaction" to the test, while that formed by the action of the polygonal cells gives a "direct" reaction. When the latter accumulates in the circulating blood, it is excreted as bile by the kidneys, but the former variety is rarely so excreted, the urine containing only an excess of urobilin. According to this conception, jaundice may be produced by (1) obstruction at any point in the biliary channels, the bile stagnant in the ducts being re-absorbed into the blood stream (van den Bergh's reaction "direct"); (2) disease of the polygonal cells, in which bilirubin, unchanged by and not excreted by these cells, passes into the general circulation (van den Bergh's reaction "indirect"); (3) disease of the liver, which may in one part involve the polygonal cells, and in another cause obstruction of the bile-channels (van den Bergh's reaction "biphasic"); and (4) excessive haemolysis, with the production of more bilirubin than the polygonal cells can change and excrete, the excess passing into the general circulation (van den Bergh's reaction "indirect").

Certain types of jaundice which will be discussed in this paper are undoubtedly due to toxins, and these types illustrate very well the important principle, perhaps even now not sufficiently realized in our attempts to understand and combat disease, that seldom if ever are morbid processes due to one factor only: practically always it is necessary to consider what may be termed the "seed" and the "soil," and often, in addition, factors which we may liken to "fertilizers" in the parallel suggested. The liver is markedly prone to suffer from the presence of certain toxins in the circulating blood, but there is an equally marked tendency for some individuals to suffer more than others. As an example of this idiosyncrasy may be mentioned the well-known tendency of certain people to become jaundiced after comparatively small doses of atophan or novarsenobillon. But, in addition to this personal idiosyncrasy, the same individual may show a greater effect at one time than at another. During pregnancy, for example, the function of the liver appears to be more easily upset. Age, too, exerts an influence: other conditions being equal, the child's liver is more prone to suffer than that of the adult, though the effect may be counterbalanced by the greater tendency to repair in the former. Poisons which exert their toxic effects on the liver usually show a maximal effect in the infant.

The study of jaundice in childhood is therefore of considerable value, and deductions drawn therefrom may often with advantage be applied to corresponding conditions occurring in adults.

It follows from what was said in the opening paragraphs of this paper that jaundice is a symptom or sign found in a variety of conditions, and is in no sense to be regarded as a disease in itself. Some of the conditions which will be discussed are clinically quite distinct and comparatively easy of diagnosis: others, though fairly obvious in typical cases, show a tendency to merge into related conditions, of totally different prognosis: as an example of the latter class may be instanced the cases of acute or subacute necrosis of the liver which appear to have commenced as so-called "catarrhal jaundice."

JAUNDICE OF THE NEWLY BORN

Jaundice is such a common sign during the early days of life that it is convenient to discuss these cases as a group.

Icterus Neonatorum (Physiological Jaundice)

Obvious jaundice occurs in a considerable percentage of infants during the early days of extrauterine life. In a still larger percentage it is masked by the pink coloration of the skin, and in these it can be rendered apparent by carefully emptying the capillaries of blood. Probably all infants at birth show an excess of bilirubin in the blood: this was so in every case of a large series I personally investigated, the results being in agreement with those obtained by Bang[2] and Ylppo.[3] The average concentration of bilirubin was 1:75,000, the normal in the adult being 1:400,000 to 1:1,000,000. Obvious jaundice does not appear before the second day, when it can usually be seen on the face, chest and back. It then makes its appearance on the upper parts of the limbs and on the abdomen. The sclerotics are the next to show the coloration, which appears last on the hands and feet. Mild cases may only show staining of the face and chest. The colour deepens for a few days and then gradually fades, fading taking place in the reverse order to the appearance, except that the sclerotics and the nails of the fingers and toes may retain the colour for a considerable time. The condition is more likely to be marked in premature babies. Except for a little drowsiness when the jaundice is deep, the health of the infant appears to be entirely unaffected, and the condition should be regarded as physiological. When an opportunity is obtained for post-mortem examination, as when death follows a birth-injury, it is of interest to note that staining of the tissues involves cartilage, cerebro-spinal

* Read in the Section of Diseases of Children at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

fluid, and the nuclei of the brain, parts not stained in other forms of jaundice.

Many suggestions have been made in order to explain the origin of the jaundice—cooling of the skin after birth, compression of bile-ducts by dilated liver veins, re absorption of bile from the alimentary tract, post natal infection, and obstruction of the bile-ducts by mucus. Obstruction has not been demonstrated; indeed, all the evidence is in favour of a considerable flow of bile into the alimentary tract, and no striking evidence has been adduced in favour of infection. Observers were naturally impressed by the advent of jaundice after birth and sought post-natal causes to account for it.

In an attempt to investigate this problem some seven years ago, I was impressed by the high value of the bilirubin in the umbilical vein at birth. While the work was being conducted, an opportunity occurred to examine a case of paroxysmal haemoglobinuria; an attack was induced by immersing one of the patient's legs in cold water; although haemoglobin did not appear in the urine till six hours later, the plasma gave a well-marked indirect reaction to van den Bergh's test within half an hour. It appeared that quite a short time was sufficient for the production of an excess of bilirubin in the blood, and it was therefore possible that in the case of the newborn infant the jaundice was due to changes occurring during parturition.

Through the kindness of a number of obstetric surgeons, I was able to obtain specimens of blood from infants delivered by Caesarean section under spinal and under general anaesthesia. These all showed quantities of bilirubin in the blood of the same order as was found in infants delivered *per vias naturales*. In a series of cases of induced abortion, bilirubin was present in small amounts between the fourth and fifth months of gestation, and in increasing amounts up to term. After birth, there is a sharp rise in the value up to the third or fourth day, and then a gradual decline, till at the fourth to the sixth week the normal value is attained. It would appear that the post-natal rise differs in degree only from that occurring ante natally. Before birth, the foetus has two possible methods of excretion—through its liver and its own alimentary tract, and through the placenta into the circulation of the mother. At birth, the second method is withdrawn, and the liver of the infant must take upon itself the entire work of excretion. It is possible that the liver may be some time after birth before assuming its full function, the presence of bile salts in the pericardial and other body-fluids supports such a supposition, and similar delays are found in the case of the kidney and of the alimentary tract. Such a supposition might explain the degree of the post-natal rise.

There is another consideration which bears on this problem. During intrauterine life, haemosiderin is deposited in certain organs of the foetus, and a study of the age of the foetus in relation to the extent of the deposit suggests a parallel to the bilirubinaemia. Immediately after birth there is a considerable degree of haemolysis, and this may also account for the increase in bile-pigment in the blood after birth. Such an explanation would regard the condition as being allied to a haemolytic anaemia. In work carried out in association with M. Maizels,[4] it was found that in pernicious anaemia and other haemolytic anaemias there was a large difference in acidity between the red cells and plasma, the degree of this being correlated with the degree of haemolysis. In all these cases, the difference was due to increased acidity of the cells, that of the plasma being about normal. In a few observations I have had the opportunity of making on blood from the umbilical vein of newborn infants, the reaction of *both* plasma and cells has been more acid than normal, the *difference* being about equal to the normal difference found in the adult. Further observations tend to show that an increase in the alkalinity of the plasma has comparatively small immediate effect on the reaction inside the red cells. Under conditions where the plasma becomes more alkaline, a condition of the red cells would be established, comparable to that found in haemolytic anaemias—i.e., there would be a large difference in acidity between the red cells and plasma. In the placenta, where the plasma of the foetus becomes oxygenated by the mother's blood, such conditions would be to some extent realized; and after birth, when pulmonary respiration is established, to a much more marked extent.

The observations on which these remarks are based are few, and estimations other than on blood from the umbilical vein are exceedingly difficult, but if further work confirms them, a definite theory can be advanced for the explanation of icterus neonatorum, an explanation certainly independent of bacterial invasion of the alimentary tract, which is the basis of a theory still held by a number of authorities.

Icterus Gravis Neonatorum

I have discussed at some length the benign icterus neonatorum because of its similarity to another condition, which if untreated is almost invariably fatal. This is a condition tending to recur in successive members of the same family, though often the first-born escapes. Of 130 cases collected by Sir H. Rolleston[1] in 1920, 77 per cent. proved fatal, and in an account which I published in 1929,[2] 83 per cent of 90 untreated cases occurring in 17 families had been fatal. The condition appears to be commoner than the published figures suggest. From the returns of the Registrar-General for England and Wales, it appears that during the seven year period from 1921-1928, at least 1,800 infants died of jaundice during the first four weeks of life, without obvious cause, such as *sepsis, syphilis, or obliteration of the bile-ducts, and* in arriving at this figure all deaths from such conditions as umbilical sepsis have been deducted from the figures for jaundiced infants—although only a proportion of these develop jaundice: the figure, therefore, probably errs in being too low. Personal communications from doctors, and the histories in more recent cases which I have seen, suggest that many lives are still lost from a condition which is in many cases probably open to successful treatment.

The jaundice usually appears within twenty-four hours, and may be noted a few hours after birth, or even in a few instances at birth. The colour then rapidly deepens. At birth, apart from possible jaundice, the infants appear strong and healthy, but with the increasing jaundice become drowsy, take the breast poorly, and lose weight. The liver and spleen are not usually enlarged, indeed, it is suggested that cases with considerable enlargement of these organs probably belong to a different group, for there can be little doubt that the group is a composite one. The temperature usually tends to be sub-normal, but occasional cases show a considerable rise, here, again, in several instances there has been evidence of maternal toxaemia during the pregnancy—a condition strikingly absent in the majority of cases—and the cases probably belong to a separate group, from the point of view of treatment it seems important to recognize this differentiation. The stools are normal in colour and the urine is dark, containing an excess of urobilin and at times bile. Haemorrhages may occur near the end, particularly in the subcutaneous tissues over the forehead, where they give rise to a bruised appearance, not to be confused

with the spider-naevi which are common in all jaundiced babies. The infants become increasingly anaemic. Towards the end there are often attacks during which the infant's face shows a peculiar shade of greyness mixed with the icteric tint. In these attacks respiration is very shallow and the pulse is barely perceptible. Often there are convulsions, and the child usually dies in coma within three weeks of birth. In all cases the Wassermann reaction is negative, and at necropsy there is nothing to suggest a syphilitic basis: indeed, the post-mortem appearances are very like those of the simple icterus neonatorum.

Excluding such cases as those of Nason,[7] Tylecote,[8] Rolleston,[9] Smith,[10] and Ritchie,[11] and a number of cases within my own experience in which there was evidence of maternal toxaemia, the resemblance to physiological jaundice is sufficiently striking to suggest a common basis. Assuming a delay in assumption of hepatic function in the simple variety, a lesser competency on the part of the liver or an increased haemolysis in icterus gravis might result in a fatal toxaemia. Working along these lines, in young rabbits it was found that injection of haemolytic products invariably retarded growth, though proportionate amounts in older animals appeared to have little effect: in the pregnant animal the procedure resulted in the death of the foetuses *in utero*, and in two such cases in which the pregnancy was early there was the formation of a mole. It is of interest that in the animals which survived, the teeth became green, and remained so until the part of the tooth affected was worn away; green teeth have been reported in icterus gravis by Thursfield and Langmead.[12]

If toxaemia be due to haemolytic products, treatment should be directed to decreasing haemolysis. Experimental work suggested that serum might have this effect, and for this reason human serum has been given intramuscularly in these cases in amounts of about 15 c.cm. daily for three or four days. In 22 out of 23 cases I have personally treated, the recovery has been perfect, and the remaining case was practically *in extremis* when seen. In marked examples of simple icterus neonatorum, serum seems to have led to more rapid subsidence of the condition. In other cases in which the liver and spleen were enlarged, or in which the infant was pyrexial, the results have not been so good: the jaundice has subsided, but the infant in some cases has died of complications, such as cerebral haemorrhage or haemorrhage into the suprarenals. In these cases I have for some time associated the injection of serum with the inunction of mercurial ointment, which in many cases gives good results, though not so strikingly satisfactory as in the main group, in which, if recovery occurs, it appears to be complete. One such case is of sufficient interest to record.

The child was born at full term. Jaundice appeared within twenty-four hours and progressively deepened. When seen on the fourth day, the lower edge of the liver extended to the umbilicus: it was fairly hard, but not as hard as that usually found in obstruction of the bile-ducts. The spleen could be felt one inch below the costal margin. The head was retracted, and the fontanelle was rather full. Meconium had been passed, and the stools contained bile. The child was comatose. Lumbar puncture showed bile-stained fluid containing blood. The Wassermann reaction was negative. The child was treated with injections of serum and with daily inunctions of mercurial ointment. She appeared to make a good recovery and liver and spleen became impalpable: now, two years later, she shows a well marked cerebral diplegia.

It is of interest that Spiller[13] has reported four cases of cerebral diplegia in association with icterus gravis. I have twice encountered it in association with congenital obliteration of the bile-ducts, of which the case recorded may have been another example. Head retraction does not necessarily mean haemorrhage: one of the most marked cases I have seen in association with jaundice was one of obliteration of the ducts, and at necropsy there was no evidence of haemorrhage, but intense bile-staining of the cerebral nuclei, especially the lenticular nuclei.

Congenital Obliteration of the Bile-ducts

In this condition, jaundice is usually manifest on the second day and is progressive, though the degree is variable. Meconium is usually passed, and this is followed by pale stools. Occasionally the stools are white from the beginning: on the other hand, the passage of meconium may be followed by pale stools which contain a fair amount of bile pigment. The urine is dark and contains bile. The liver is large, even after death, thus contrasting with the enlarged liver of obstructive jaundice at a later age; but the clinical observation which impresses one most is the extreme hardness of the organ. The spleen is also enlarged in the majority of cases. The condition runs a variable course, and the infant is often surprisingly fit till late in the disease, when wasting may be marked. There is, however, a great tendency to haemorrhages from the mucous membranes and subcutaneously. Often, too, there are periods of pyrexia, sometimes accompanied by convulsions, though these usually only occur terminally. According to Weber,[14] the cerebro-spinal fluid does not contain bile, but in cases of my own, in which death has occurred early, the fluid has been stained, and in one case referred to above the cerebral nuclei were very deeply stained. At necropsy there is usually complete obstruction to the flow of bile, the obstruction in the majority of cases being extra-hepatic; the lower part of the common bile-duct may be represented by a fibrous strand. The lumina of the ducts above the obstruction are not dilated, thus contrasting with the condition usually found in adults as the result of obstruction. The hard, enlarged liver shows evidence of biliary cirrhosis, and is often dark green in colour. The glands in the portal fissure may be enlarged. Syphilis has been suggested as a cause, but there is no evidence for this either in the Wassermann reaction on parents and infants, or in section of the organs after death.

Two main theories have been advanced to account for the condition. First, that supported by Thomson,[15] Beneke[16] and Milne[17] suggests a developmental narrowing of the ducts, giving rise to partial obstruction, predisposing to a catarrhal condition which completes the obstruction. The stagnant bile is presumed to be toxic, and this, it is suggested, gives rise to the cirrhosis. In support of the theory it may be mentioned that the condition has on rare occasions been associated with other congenital abnormalities, as for example hypertrophic stenosis of the pylorus (Barker and Mackey),[18] and in two cases recorded by Poynton and Wyllie[19] in association with congenital heart lesions—one of these also showing deformity of the feet and the other occurring in a mongol.

The experiments of Rous and Larimore[20] are of interest in the discussion. By obstructing the large bile-ducts they produced a stellate fibrosis around them; obstruction in the intra-lobular canaliculi led to a diffuse intra-lobular cirrhosis; while obstruction in the small bile-ducts produced a pure unilobular cirrhosis. From the experimental point of view it would appear that the lesions, if primary in the ducts, would have to be multiple, though perhaps it is unfair to compare the foetal liver with that of experimental animals. The other suggestion, supported by Rolleston,[21] is that toxins passing from the mother through the placenta reach the foetal liver through its double circulation and are excreted into the bile-ducts: in their passage through the liver they give rise to a mixed cirrhosis, and after excretion give rise to inflammation of the

ducts, and ultimate obstruction. There is much in the latter theory which fits in with the clinical facts: the lesion is undoubtedly progressive in the majority of instances, and occasionally a patient dies before obstruction is complete, but cirrhosis is found to be advanced. On the other hand, one would perhaps expect the mother to show some evidence of the toxaemia, and this is surprisingly absent; other conditions, however, which markedly affect the foetal liver—for example syphilis—may have very little obvious effect on the mother.

Treatment, in the main, has been inefficacious. A few cases would appear to lend themselves to surgery, especially when the gall-bladder is dilated, but it must be admitted that good results from such treatment form surgical curiosities. During the last four years, I have been treating these and allied conditions by mercurial inunction. In some, serum has been given in the earlier stages with the object of reducing haemolysis and so lessening the production of bile. The results are, I think, the most promising hitherto obtained. The mercury must be pushed, suspending treatment for a time if signs of mercurial poisoning such as buccal ulceration appear, but continuing again after an interval.

One case so treated appeared to improve for a time, and was discharged for the mother to continue treatment at home. The child was later re-admitted into hospital and died. The liver had decreased in size, and necropsy confirmed that the organ was much smaller than that usually found in this condition. The common bile-duct was completely impervious. The interesting feature, however, was that above the obstruction, the bile-duct was greatly dilated and contained a large quantity of bile. The case is suggestive of partial recovery.

From experience of the use of mercury in other conditions of the liver, I have formed the impression that it is more likely to be beneficial when the smaller bile-ducts are mainly involved, and the results of treatment so far support the theory of a descending change rather than the reverse. Other cases of biliary cirrhosis show on the whole fairly satisfactory results from the same form of treatment, though it must be stated that the older the patient the less satisfactory have the results been.

Syphilis

Congenital syphilis may rarely produce a peri-cholangitis with enlargement of the liver and spleen. The liver is firm, but not so hard as that found in the previous condition; it is usually tender. Jaundice is not rare in this condition, though it is usually absent; it is probably due to inflammation of the small bile-ducts, though occasionally it may owe its origin to enlarged lymph glands. When jaundice is present at all, the infants are usually icteric when born, but it may commence weeks later, and then may be recurrent and associated with multiple haemorrhages: such cases are possibly due to secondary infection. Other evidence of syphilis is usually present, and the infants are debilitated, wasted and anaemic, with a tendency to vomiting and diarrhoea. The treatment of the condition is well known and needs no amplification here, save to stress that, unless it is persisted in, relapses are common. In gauging the effects of treatment it should be remembered that the results of the Wassermann test on the infant may be fallacious.

Toxic Jaundice

Jaundice in the young infant may be associated with sepsis of the umbilicus or with alimentary infection (cf. Winckel's disease and Buhl's disease). Such infants are extremely ill, and the extremities are usually cyanosed. There is a very marked tendency to haemorrhages. In the less marked cases, the temperature is generally raised, but in the worst forms, may be sub-normal. The condition usually rapidly progresses to coma and death, though the end may sometimes be delayed for weeks by vigorous treatment.

Epidemic Infective Jaundice (Catarrhal Jaundice)

Of cases of jaundice occurring at a later age, the commonest are examples of so-called catarrhal jaundice. The name is bad, implying as it does the original conception of an obstructive jaundice, secondary to plugging of the ducts with mucus—an explanation which has been offered in so many different types of jaundice and almost without exception proved to be incorrect. On rare occasions the condition has occurred in pandemic form, but is usually met in epidemics or sporadically. The causal virus is unknown. Apart from possible relapses during the course of the complaint, it appears to confer a lasting immunity. It is essentially a disease of childhood, but may be encountered in adults. The age incidence is of interest in that adults may have increased general resistance, or may have had the condition previously without manifesting the main symptoms. Cases illustrating the latter occur during epidemics; Wallgren [2] stresses their incidence, and I have personally encountered the case of a child with typical catarrhal jaundice in whose sister the only abnormality found was a temporary enlargement of the liver; this was only discovered during the course of a routine examination which I was at that time conducting.

It is well known, of course, that a child may be brought to the doctor for malaise alone, the jaundice being so slight that it is not noticed by an untrained eye. It appears more than likely that some patients acquiring the disease may have only the slightest symptoms. A consideration of increased resistance with age is also of interest. During epidemics, I have encountered two families in which in one instance three children out of seven, and, in the other, two out of five acquired the disease; the five who became jaundiced gave a very strong history of cyclical vomiting, such a history being entirely absent in the remaining members of the families. It is well recognized that cyclical vomiting is pre-eminently a condition of childhood, and whatever its exact etiology may ultimately prove to be, it is generally admitted that the liver plays a part in the manifestation. It is, of course, not suggested that catarrhal jaundice only occurs in the subjects of cyclical vomiting, but the example given does suggest that the "soil" is of importance. In the same connexion, the effects of toxins on the liver at various ages have already been referred to. The maximal incidence appears to be between the ages of five and ten. The majority of the cases occur in the autumn.

At the onset there is usually slight fever, but in cases not seen early this is generally missed. The first symptom as a rule is malaise, associated with anorexia: nausea and vomiting are not uncommon. Jaundice then makes its appearance, first noticed in the sclerotics; the liver becomes enlarged and tender, the enlargement often being associated with pain in the epigastrium and over the right lobe of the organ; the urine is dark with bile, and this may be the first manifestation noticed by the parents; the stools are pale, both from diminution or absence of bile, and from excess of fat associated with the same deficiency; the spleen is enlarged in a fair proportion of cases. Van den Bergh's test usually gives a positive direct reaction in the earliest stages, and thereafter is biphasic. The rapid and tender enlargement of the liver is presumably due to vascular engorgement, and usually precedes the diminution of the flow of bile; the degree of enlargement bears no direct relationship to the depth of the jaundice. The picture suggests a hepatitis, and this is confirmed by sections of the liver

taken from living patients by Nordmann[23] and Eppinger, and also by sections obtained from patients who have died from other causes (Eppinger[24]).

The course of the disease in the vast majority of cases is uneventful, though the duration of symptoms is variable; the liver in many cases may be enlarged for weeks after all jaundice has disappeared; it is no longer tender, but remains as evidence of a hepatitis which has not entirely subsided. When the jaundice does not rapidly subside, it must always give rise to a doubt as to whether the case may not be one of subacute necrosis of the liver; and occasionally cases suddenly take on grave characters and pursue the course of acute necrosis. How far these were originally true examples of the condition under discussion is difficult to prove, but it is suggestive that during the epidemic in Gotenburg between 1924 and 1926, there were more cases of this grave type than in other years, and that the increase of such cases was confined to the epidemic area. Such statistics are fortunately easy to obtain, the condition being a notifiable one in Sweden. In epidemics, cases may be seen in which the jaundice recurs; how far such cases are due to the original virus, and how far to superadded infection in a patient whose liver has not fully recovered from an inflammatory attack, is again difficult to say. If seen for the first time in the second attack, such cases may readily be diagnosed as biliary cirrhosis, for prodromal symptoms are usually absent. One of Wallgren's cases,[22] occurring during the Gotenburg epidemic, I quote rather fully, as it demonstrates many of the points under discussion, though unfortunately he does not prove a source of infection by contact in this case:

A boy, aged 14, was taken ill in April, 1926, with some fever, vomiting, and abdominal pain. Jaundice developed and the condition was diagnosed as catarrhal jaundice. The icterus subsided and in May he is stated to have been perfectly well. Later, he suffered from attacks lasting about two days, during which he "felt ill," complained of pain in the abdomen, and became icteric. The urine contained bile. At the end of August, he was admitted to hospital. The liver was not palpable and appeared small. The spleen was greatly enlarged. There was no ascites. The temperature was normal; the pulse rate about 80. The urine contained bile. The red cells showed slightly increased resistance to hypotonic salines. The haemoglobin was 80 per cent., colour index 1.2. The Wassermann reaction was negative. After investigation, he was sent home under the care of his doctor. On October 11th, he had a sore throat with raised temperature, and vomited blood. He was again admitted to hospital, where he had repeated haematemeses, and passed dark blood per rectum. The haemoglobin fell to 40 per cent. and the patient died. At necropsy, the veins at the cardiac end of the stomach were grossly varicose and presumably formed the site of the bleeding; the spleen was enlarged, the surface being irregular; the liver weighed only 891 grams, and had a nodular surface, each nodule being about the size of a hazel nut. On section, the nodules showed a yellow-brown surface with spots of a greyish colour. The bile-ducts showed no obvious abnormality. Histologically, there was much fibrous tissue, with many cells showing an obvious attempt at regeneration; there was, however, an entire absence of lobular arrangement.

Marchand,[25] and Pratt and Stengel,[26] have recorded similar cases, occurring almost entirely in children. With Mallory, they regard the condition as a "toxic cirrhosis"—an attempt at regeneration after an acute process.

The condition is obviously infectious. During epidemics, cases arise, in which after the most careful search no direct contact can be established; and this is an argument in favour of the existence of carriers. It would appear that cases must be regarded as infectious both during the prodromal period and for some time after the jaundice has subsided. It is certain that infection may take place during a short interview; there is no evidence in favour of infection through the alimentary tract. In some cases, a running ear appears to have been responsible for spreading the infection. The incubation period is difficult to establish. During epidemics the majority of cases appear to develop the condition between 21 and 28 days after contact. A few appear to occur after one or two weeks, but in these it is difficult to exclude a previous contact. In Wallgren's cases, occurring among patients who were in hospital at the time of actual infection, the average time was about 21 days.

From the point of view of treatment there is little to add to that commonly advocated, but I would condemn the use of atophan suggested by Grunenberg and Ullmann,[27] as being contraindicated in a condition which appears to be essentially an acute hepatitis. In those cases where a graver condition is suspected I think that intravenous glucose, together with small doses of insulin, may be of considerable value, as also may be the administration of calcium, given intravenously in the form of a 10 per cent. solution of the gluconate.

Other Conditions with which Jaundice is Associated

It is not possible in this paper to discuss fully the association of jaundice with *Mumps*. Usually, it follows the enlargement of the salivary glands, but may occur apart from this. Possibly the occurrence of diarrhoea, and the greater degree of abdominal pain, not so obviously associated with the enlargement of the liver, may help in the differentiation from the previous condition. *Cholangitis, Cirrhosis,* and *Haemolytic Jaundice* are conditions which might profitably have been discussed, and I hope that we may hear something of them from subsequent speakers.

There are many other conditions which may be associated with jaundice in childhood, examples being infective conditions such as pneumonia and typhoid fever, syphilis in forms other than that discussed above, heart failure, and such rare conditions as Wilson's disease, and obstruction due to gall-stones; but I have confined myself in the main to a short survey of comparatively common conditions, where suggestions as to pathology and treatment may, I hope, form the basis of a discussion not entirely without profit to us.

EXOPHTHALMOS OF CENTRAL ORIGIN *

BY

W. RUSSELL BRAIN, M.D., F.R.C.P.

ASSISTANT PHYSICIAN, LONDON HOSPITAL, ROYAL LONDON OPHTHALMIC HOSPITAL, AND HOSPITAL FOR EPILEPSY AND PARALYSIS

By exophthalmos of central origin I mean exophthalmos occurring in connexion with signs clearly pointing to an organic lesion of the central nervous system. In the short time at my disposal I can give you only a brief account of these associated symptoms and their pathological bases, and then show you the photographs of ten patients illustrating these points which I have chosen as representative, from a total of between twenty and thirty patients.

The following clinical features appear to me to be of special importance. (1) Exophthalmos may be associated: (*a*) with supranuclear ocular palsies, especially with paralysis of conjugate vertical movement and convergence; (*b*) with external ophthalmoplegia—some of these cases are etiologically obscure and exhibit bizarre defects of ocular movement; and (*c*) with internal ophthalmoplegia—in one case unilateral exophthalmos was associated with an Argyll Robertson pupil in the same eye; in another the reaction to light was sluggish in both eyes. (2) Exophthalmos may be unilateral or bilateral, and if bilateral it may be equal or unequal in degree on the two sides. (3) It may be associated with lid retraction, or with ptosis, either of which, again, may be unilateral or bilateral, and equal or unequal. There may be lid retraction on one side and ptosis on the other. (4) Exophthalmos may occur with or without enlargement of the thyroid. (5) It may occur with or without disturbance of sugar metabolism.

A wide range of combinations of these disturbances is encountered.

Pathology

The lesions associated with exophthalmos are pathologically varied and usually obscure; I have no post-mortem material. Encephalitis lethargica is responsible for a small number, usually with Parkinsonism. Several have high blood pressure, though in only one case is there evidence that the lesion was vascular. One patient falls into the group of internal ophthalmoplegia with absent tendon reflexes. Several can only be described as nuclear ophthalmoplegia of unknown origin. The most important single group is that in which ophthalmoplegia is associated with enlargement of the thyroid, though the relationship between the two is difficult to explain. Some of these cases have been described as myasthenia gravis associated with exophthalmic goitre. On clinical grounds it is clear that the lesion is usually situated in the mid-brain.

Case I

The patient is a man, aged 59, who in 1927 had an illness which appeared to be encephalitis lethargica. Since then he has developed a bilateral progressive exophthalmos. He has lost conjugate ocular deviation upwards, and convergence is almost lost. There is no thyroid enlargement. His pulse rate is 72; he has lost no weight, and has an increased sugar tolerance, with a low renal threshold.

Case II

The patient is aged 24. She began to develop Parkinsonism two and a half years ago, and now has generalized tremor and rigidity, with attacks of oculogyral spasm. She has bilateral exophthalmos, more left than right, and ptosis. There is no thyroid enlargement.

[In another case of encephalitic Parkinsonism bilateral exophthalmos was associated with lid retraction, weakness of ocular deviation upwards, sweating, tachycardia, hyperglycaemia, and glycosuria, but the thyroid was not enlarged.]

Case III

In 1917 the patient, a man, developed exophthalmos, tachycardia, and external ophthalmoplegia. His condition has been stationary since. He has bilateral exophthalmos and lid retraction, with partial external ophthalmoplegia. His blood pressure is 160/80; his pulse rate is 96, and he has glycosuria. His thyroid is not enlarged, and there has been no loss of weight.

Case IV

The patient is a man aged 52, with a blood pressure of 230/120. He recently had a stroke, which left him with sensory aphasia and right homonymous hemianopia. After this he gradually developed bilateral exophthalmos with lid retraction. He has a diabetic curve in his sugar tolerance test. His thyroid is not enlarged.

Case V

The patient is a girl, aged 23, who exhibits the syndrome of internal ophthalmoplegia, with absent tendon reflexes. In addition she has unilateral exophthalmos with lid retraction.

My last five patients all have an enlarged thyroid.

Case VI

This patient has for six months had unilateral exophthalmos of the left eye, lid retraction, and tremor of the left hand. Her pulse rate is 108; her thyroid was not enlarged at first, but it became slightly swollen later.

Case VII

This case, that of a girl aged 25, may be called a typical case of exophthalmic goitre, except that the patient has bilateral exophthalmos, associated with lid retraction on one side and ptosis on the other.

Case VIII

This case, for which I am indebted to Dr. Symonds, resembles Case III in exhibiting external ophthalmoplegia with unequal bilateral exophthalmos. The ophthalmoplegia developed first, being followed by the exophthalmos, which is associated with ptosis. The thyroid is enlarged, and there is tachycardia, hyperglycaemia, and glycosuria; there has been loss of weight.

Case IX

The patient is a woman, aged 41, who developed acutely bilateral exophthalmos, ptosis, loss of convergence, and conjugate deviation downwards, and a myotonic reaction of the pupils on accommodation. The thyroid is enlarged and nodular; there is tachycardia. The blood sugar is normal.

Case X

A woman aged 59 began four and a half months ago to suffer from diplopia; at the same time the right eye became prominent. She feels nervous, and complains of palpitations. She has always been thin, and has lost 6 lb. in the last two years. The pupils react sluggishly to light. There is marked right exophthalmos, with bilateral lid retraction and marked weakness of upward deviation of the right eye. There is a rounded enlargement of the right lobe of the thyroid the size of a walnut; tremor of the hands, pulse rate of 100, and a blood pressure of 190/100. The blood sugar curve is normal, and the Wassermann reaction negative.

The cases I have described raise many difficult questions which I hope to discuss more fully later. All I can say now is that there seems to me to be no sharp line dividing exophthalmic goitre from certain cases of acute and chronic lesion of the nervous system, involving especially the upper part of the mid-brain.

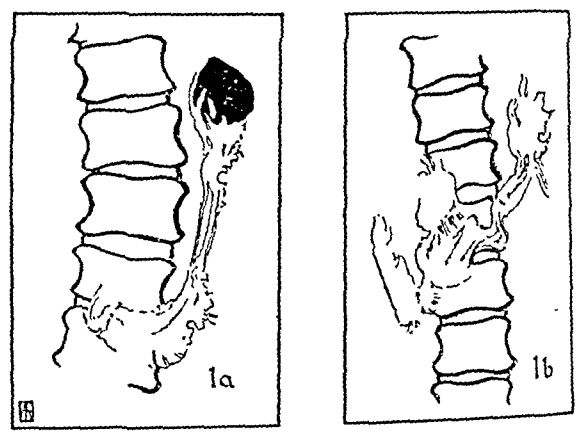
THE SKELETON BARIUM MEAL IN GASTRIC DIAGNOSIS

BY

T. D. OVEREND, B.A., M.R.C.S., L.R.C.P.,
D.M.R.E.CAMB.
RADIOLOGIST TO THE BUCHANAN HOSPITAL, HASTINGS

It has long been customary to commence the radiological examination of the stomach by watching the first mouthful of barium swallowed and looking for a fleck of barium held up in an ulcer niche if this were present. If this first mouthful is spread over the interior of the stomach by palpation a good view of the relief pattern of the mucosa is often obtained. But this procedure has its limitations; the ordinary barium meal is not perfectly adapted for the demonstration of the mucosa, and, in spite of the fact that much work has been done on the subject, it may be said that the study of the alimentary mucous membrane has not yet received the attention it deserves. Some of this neglect is due to the incompleteness of our knowledge of the great variations which may occur in the appearances of the normal relief pattern. Nevertheless, the study of the gastric mucosa is by now a valuable supplement to the usual radiological investigation, and the method of the "thin film," or skeleton meal, reveals details that cannot be otherwise discovered.



The systematic radiological study of the gastric mucosa originated with Forssell, and was extended to the duodenum by Akerlund. The evolution of a technique for clinical use is due to numerous authorities, the chief of whom, in addition to those already mentioned, are Gutzeit, Chaoul, and especially Berg. These workers have greatly enlarged the scope of the gastric examination and have paved the way to a genuine comprehension of the conditions underlying the appearances seen.

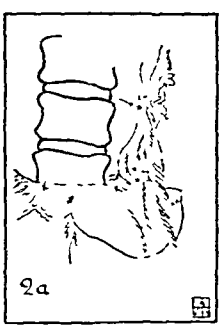
TECHNIQUE

The procedure for the demonstration of the gastric relief pattern varies slightly with different authors. The essential preliminary is the preparation of a solution adapted for adhering to the mucosa. Berg uses a solution of 250 to 300 parts of barium sulphate to about 400 of water; Chaoul uses about the same proportions with the addition of small amounts of tragacanth, spirit, and amyl acetate. A useful solution is the following: 10 ounces of barium sulphate, 50 grains of tragacanth powder, made up to 20 ounces with chloroform water. The patient is first examined in the supine position with a slight tilt to the left, a sip of the barium is swallowed, and the cardia screened. By palpation and changes of posture the barium is spread over the mucosa and the patient examined in the prone position with graduated compression. Further sips are given until the mucosa is perfectly covered with the preparation. It is unwise to allow the procedure to become stereotyped; each case has its peculiarities which should be studied individually. The principal sites of ulcer should be screened at every possible angle and examined at different stages of filling. Films are taken when necessary; they may be taken from below or from above the couch. Graduated compression is required to get good relief patterns. The patient is then examined standing, and if the investigation seems complete the stomach is filled with barium and examined in the usual manner. Difficulties can arise if there is excessive fluid or mucus in the stomach, as this can prevent the close adherence of the barium to the mucosa; this can sometimes be dealt with by injecting 1/100 grain of atropine an hour before the examination.

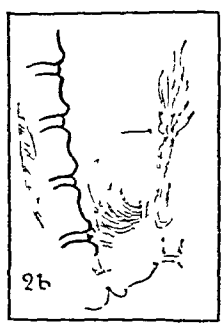
NORMAL APPEARANCES

The normal appearances, as noted above, are subject to great variations, and different patterns appear at different times in the same stomach; this is due to the fact that the pattern depends largely on the state of contraction of the muscularis mucosae. A constant feature is the presence of four well-marked longitudinal ridges, visible on oblique illumination, running down the lesser curvature; these enclose the stomach path of Aschoff, which is the chief ulcer-bearing area. Towards the greater curvature the longitudinal folds become more and more tortuous, and transverse folds appear. A serration on the greater curvature in the completely filled stomach has long been noted; it was considered by some authorities to be a sign of chronic gastritis. It is probably due to the formation of strong transverse ridges in the mucosa caused by local contraction of the muscularis mucosae, these ridges acting as slings to support the heavy part of the filled stomach. Under normal conditions the relief pattern is delicate and easy to deform or obliterate by palpation; pathological changes cause it to stiffen; it then becomes permanent and cannot be altered by pressure. Slow alterations in the pattern can sometimes be observed, and the part played by the muscularis mucosae in evacuating the stomach forms the subject of an interesting paper by Sick. Fig. 1a shows a fairly normal relief pattern in the standing position.

CHRONIC GASTRITIS



In hypertrophic gastritis the folds of the relief pattern are thickened and stiff; in atrophic gastritis they are very delicate and may be partly absent. Difficulties arise from the fact that hypertonic stomachs have strongly marked folds resembling those of hypertrophic gastritis, while atonic and dilated stomachs show delicate folds like those of atrophic gastritis. Great irregularity and stiffness of the folds favours the diagnosis of gastritis, and a still more trustworthy sign is the presence in the relief pattern of rounded or oval translucent islands due to patches of atrophy. Much of the work on gastritis has been done by Gutzeit, using gastroscopic control. It should be mentioned that the distension of the stomach by gas in gastroscopy has a tendency to obliterate the ridges which form the relief pattern.

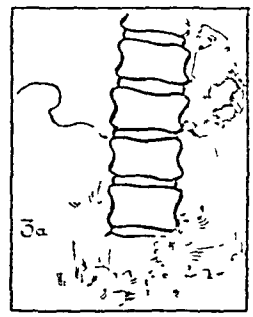


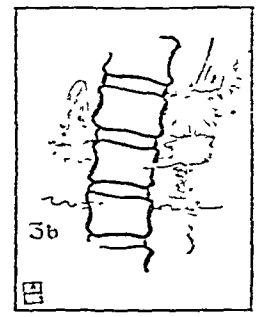
Korbsch relies on indirect signs in the diagnosis of gastritis, as increased tone and peristalsis, serration of the greater curvature, local tenderness, etc. Although the diagnosis of gastritis by the skeleton meal is by no means easy or free from the possibility of error, there is little doubt that when its normal appearances are better known it will be found more reliable than any method depending on indirect signs. All the signs enumerated by Korbsch can be found in conditions other than gastritis, and the serration of the greater curvature is found in stomachs that are innocent of any pathological change. Fig. 1b shows gastritis in a case of cholecystitis.

The gastritic changes concurrent with gastric ulcer and carcinoma are of great interest, and it has even been suggested that their study may enable us to foretell the later onset of ulcer and carcinoma. This, perhaps, is unduly optimistic, at any rate as far as carcinoma is concerned, but the study of the relief pattern may shed some light on the factors at work. Another interesting field of study is provided by the cases of gastritis following gastro jejunostomy.

Peptic Ulcer

In the skeleton meal, as in the full meal, the direct evidence is given by the actual niche. There are both advantages and disadvantages in the former procedure; it is sometimes difficult to fill the niche when the main cavity of the stomach is empty. On the other hand, in ulcer of the cardia, and in ulcer of the corpus away from the sky-line of the lesser curvature, as well as in pyloric and pre-pyloric ulcer, the filling and visualization of the niche is often very much easier in the skeleton meal. The conditions of the mucosa around the ulcer can also be studied. Barclay has emphasized the fact that the apparent size of an ulcer depends on the heaping up of the mucosa around it; so the decrease in size of a niche under treatment can be misleading. The presence of radial striæ in the mucosa converging on the site of an ulcer is another valuable sign. Duodenal ulcer can often be diagnosed by the skeleton meal, but the best method is that described by Akerlund, Attinger, and Berg. This is, to fill the duodenal cap completely by pressure on the stomach and on the descending duodenum. The cap is then examined at all possible angles for contour deformities, and then completely emptied by compression or manipulation and examined again for any residue in a niche. The skeleton meal is especially well adapted for the diagnosis of jejunal and gastro-jejunal ulcer, and also for the differentiation between ulcer and diverticulum. Fig. 2a shows a small ulcer niche on the lesser curvature,





with interruption of the mucous folds from infiltration; Fig. 2b shows a small diverticulum of the lesser curvature with normal folds running into it.

Carcinoma

The patient with carcinoma of the stomach too often has a well marked filling defect by the time he comes for investigation. In such a case the examination of the completely filled stomach often gives an easy diagnosis. The skeleton meal here finds its application in determining to what extent the growth has penetrated into the stomach walls beyond the actual filling defect, and it may give valuable information as to the mechanical, as apart from the metastatic, possibilities of resection. It is also of value in the diagnosis between chronic callous ulcer and the malignant ulcer; according to Haudek and Barclay the mucous membrane is abruptly cut off in carcinoma, while in simple ulcer it has an infolded appearance. It is probable that a break in the relief pattern caused by a growth could be recognized long before the formation of a filling defect. Striation of the mucous folds "against the grain" is considered by Berg to be an early sign of carcinoma; I have seen it in the neighbourhood of an early growth.

Fig. 3a shows the relief pattern in a case in which the growth had penetrated far beyond the filling defect; the

extension in the gastric wall is seen high in the cardia, while the filling defect is low in the body. Fig. 3b shows the pattern in a case that had a large filling defect in the corpus; the mucous folds of the upper third of the stomach are seen to be free from invasion, partial gastrectomy was successfully performed.

THE SHAPE OF THE PELVIC BRIM AS THE DETERMINING FACTOR IN CHILDBIRTH*

BY

KATHLEEN VAUGHAN, M.B. Lond.

LATE SUPERINTENDENT, DIAMOND JUBILEE ZENANA HOSPITAL, SRINAGAR

Those who practise midwifery in the East, whether in India or in China, are soon aware of the fact that under certain conditions of life childbirth is easy and safe, while the opposite conditions render it difficult and dangerous for both mother and child. The field worker, the woman who lives out of doors tending the cattle, planting out crops often knee-deep in cold water in the rice fields, rowing the heavy boats used for transporting grain, the tent dwellers—such as the women of the nomadic tribes on the North-West Frontier of India—all these have

* A paper read in the Section of Obstetrics at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

their children safely and with no more difficulty than the animals around them have in parturition. On the other hand, the city dwellers, and especially women who on account of the custom known as " purdah " must remain in seclusion and live indoors from 8 years old and onwards—these women find their confinements increasingly difficult and dangerous for themselves and their offspring. In China, the women who bind the feet are the class from which the difficult obstetric cases come.

That it is not a racial question, but due to a certain manner of life is seen when, on inquiry, one finds that women of the same race and even of the same family in open-air surroundings have easy confinements, while part of the family who have migrated to the town after some years suffer as the townspeople do. The negress provides a good illustration. In her natural surroundings she gives birth to children with ease, but in America, living in big cities such as New York and Baltimore, Whitridge Williams tells us she has more obstetric difficulties than the American white woman herself, and he suggests that this must be due to something in the manner of life in the crowded quarters of great cities.

In the Carnegie Trust Report for 1917 we read of easy labours and large families among the Highland women who, bare-footed, haul in the nets with the men, follow the plough, and engage in field work, and mention is made by local authorities of the tinker women who live in tents and whose custom it is to be delivered safely and rapidly by the roadside before any doctor or nurse can be called to assist. Strong contrast, this, to the maternal mortality rate and the infant death rate to be met with in cities such as Edinburgh and Glasgow. In England we still have our gipsies and canal-boat women, with their large families and easy and safe confinements, and yet our maternal mortality rate shows no decrease in the last twenty years, and industrial towns like Swansea, Cardiff, Barnsley, Bradford, and Rochdale head the list with their maternal death rates.

The fundamental cause of difficulty is obvious: that for some reason the child's head and the mother's pelvis do not fit, and delayed and difficult labour is the result; bruising of soft parts, exhaustion of the mother, the risk of sepsis—all these things follow on this primary failure of adaptation. Is the foetal head too big or the maternal pelvis too small?

In the hope of getting some light on this problem I consulted Sir Arthur Keith, who told me he thought that undoubtedly the heads of the race were getting larger among civilized peoples, but the pelves of the race did not seem to keep pace with them. With his permission, therefore, I was allowed to examine and measure any specimens I wanted at the Royal College of Surgeons.

There were two factors to be considered: (1) the unyielding pelvic brim of the mother; (2) the yielding foetal head which passes through the brim.

The Brim of the Pelvis

It was at once noticeable what a variety of shapes the female pelvic brim assumed—kidney-shaped, oval, round, Y-shaped, and irregular, or one side larger than the other. Verneau in 1875 published a treatise on variations of pelvic shape as regards both sex and race, but he found, like our obstetricians of to-day, that the female pelvis was subject to such extreme variations in shape, *even in the same race*, that in the end he confined his observations almost entirely to the male pelvis among the different races of mankind. But my object was to find the area available for the passage of the foetal head through the brim. A piece of string was used and carried round the brim following the ilio-pectineal lines, then across the back of the pubic symphysis, and, in order to keep in the plane of the brim, it was carried across the sacrum just below the promontory.

It is obvious that the same circumference arranged as a circle encloses a larger area than the same boundary line arranged in any other form, and that, circumferences being equal, the shape of the brim determines the capacity of the pelvis. How did the pelves vary from the circular form? The European—Englishwoman, Frenchwoman, and Russian—were flattened from before back, having the long diameter transverse. Then there were pelves whose brim approached the circle, and finally the Andaman Island female specimens 1216, 1212, 1213, the Bushwoman 1311, the Sikh woman 631 B, Peruvian f 1013, South Australian f 1068.15, and Negress f 1256.51, whose transverse and antero-posterior diameters are of equal length, and consequently the pelvic brim is a perfect circle. There were also innominate bones, one from Ur of the Chaldees, one from Salisbury Plain (Ancient British), and an Anglo-Saxon specimen, where the great roundness of the ilio-pectineal lines was so marked that one was led to conclude that the more primitive the habits of the life the more circular the pelvis. All these people must have borne children safely without doctor or midwife.

Turner, writing in 1866, regarded all pelves as circular if they had an index 90:100, but he dismisses such as belonging to a lower grade of civilization than the European. But are the differences in form really racial? They are not, for it was at once apparent that the round-headed race, such as the European, is born of the oblong or kidney-shaped pelvis, while the long-headed race, such as the Bushman, is born of the round pelvis, so that the variations in shape of the female pelvis serve no useful purpose. Besides, Lynch in America published x-ray studies of parturition showing that the head passing through an oval brim left the ends of the oval empty, and when we consider

The Foetal Head

we find that, unlike the pelves, which differ in shape so widely even in the same family, the part of the infant's head which engages in the pelvic brim is a circle, among all people of whatever race, whether they are dolichocephalic or brachycephalic. This is the part we know as the suboccipito-bregmatic circumference, which in full flexion is brought into the maternal brim; and it has recently been shown that it is in this plane, and in this plane alone, that the foetal head can safely be diminished in volume, while still preserving its circular form. Unequal pressure or pressure in other planes leads to tearing of the tentorium and haemorrhage, one of the commonest causes of stillbirth and also of feeblemindedness. We are reminded of a cup and ball—any departure from the circular, however slight, in the cup, will prevent the ball from entering, and so a measure just sufficient to encircle the child's head will prove inadequate if it is out of shape in the least degree.

In England and America want of light, and incorrect food, show themselves first by decalcification and decay of teeth, so that rickets must be almost universal, and, as we know, affects the bone most where growth is most rapid and calcification is proceeding most quickly. Such a part of the body is the pelvis. At puberty the brim measures more than seven times what it did at birth. It would take too long to recall the stages of development of the pelvis in detail, but we must remember that at birth it consists entirely of cartilage, containing forty-eight active centres of ossification. Shortly before puberty the three portions of the innominate bones fuse.

Sacro-iliac Joints

Duncan pointed out that pelvic development was influenced by the sacro-iliac joints, and we know that ankylosis of these joints produces atrophy of the pelvis,

and that where only one sacro-iliac joint is affected, the pelvis fails to develop only on the ankylosed side, and the earlier this morbid change takes place the more complete is the deformity produced. Whitridge Williams and Merkel have both testified to the rapid growth of the pelvis in girls just before puberty, and they draw attention to the fact that it chiefly affects all the parts near the sacro-iliac joints

In handling the pelves at the Royal College of Surgeons, I noticed how well developed the sacro-iliac joints were in native races All circular pelves have this joint well developed In all these the knob or boss on the auricular surface of the ilium was well marked and the articular surfaces extensive Havelock Charles in 1894 showed how the influence of function has modified the Punjabi sacro-iliac joints, producing a larger articular surface, which, he says, is common to all Oriental races and is similar to those found in prehistoric man

There should be in all men and women, as in Orientals, a mobility of this joint and a constant change of pelvic inclination as the subject walks, runs, sits, stands, or crouches, and the immobility of the joint leads to serious changes in pelvic shape The squatting posture used by both men and women while sitting, and also when attending to the calls of nature, was, of course, also employed by primitive man for the same purpose

In adults I find that the two halves of the pelvis can be seen and felt to move apart with change of posture This can be tested by noting the position of the anterior superior spines and the tubera ischii—first in the tiptoe position as if preparing for a dive, and again in the squatting position The whole pelvis is expanded to its utmost capacity in the squatting position, and this is most marked while the component parts of the innominate bones are still cartilaginous—that is, at any time before puberty

It is the swing of the sacrum between the innominate bones that influences the final shape of the pelvic brim, which should be a circle In India, when the girl has lived a confined life and has sat in a more or less crouching position for years, one often sees the antero posterior diameter of the pelvis lengthened at the expense of the transverse, and St John Brooke in Africa notes the change in pelvic shape in Zulu girls due to a custom prevalent among them of sitting so that their weight is borne on one thigh only.

In England the still soft pelvis is bent by long sitting at school, and this is not counteracted as it should be by the proper action of the sacro-iliac joints, which should be used daily, if only during the acts of defaecation and urination The wearing of high heels also limits and cramps their movements, the body weight is thrown forward on to the arch of the foot instead of the heel, the pelvic angle is altered, and the back unduly hollowed to preserve the balance That these facts are the real explanation of our increasingly difficult maternity is clearly seen when we compare them with conditions where motherhood is still natural and easy

Observe the habits of the Indian woman, of the Shetland woman, the tent dwellers, the boatwomen, the tinkers and the gipsies—in fact, of all those who live natural lives out of doors and exercise their sacro-iliac joints by hard manual labour, digging, weeding, hauling in nets carrying and lifting heavy weights, and, more important than all, the daily crouching posture used in attending to the calls of nature This posture is really the natural and only satisfactory one, and all these people are without the modern closet and most of them without chairs The infants are breast fed, later they have coarse but natural and fresh food They roll and kick and tumble and squat and climb and run as much as they like Their elders have perfect teeth—the only really satisfactory evidence of the absence of rickets in a community Maternity is consequently easy, the balance of the sexes well preserved because the larger-headed children are not destroyed by injury during birth, and the feeble minded are not made, as so often among us, by the *successful* attempt to force a round head through an oval pelvis

Conclusion

To sum up maternity is a natural function and is easy and safe when the pelvis of the race fits the head of the race The misfit is due to loss of area in the pelvic brim owing to a circle being bent into an oval The change is caused by rickets and disuse of the sacro-iliac joints before 14 years of age Perfect teeth are found with the round pelvis, and this is well understood among primitive people, who consider such teeth essential in a bride

[The paper was illustrated by tracings and specimens, and a preparation to show the movements of the sacro-iliac joints]

SPONTANEOUS HAEMOPNEUMOTHORAX WITH UNUSUAL POST-MORTEM FINDINGS

BY

E GERARD HOUSDEN, M D Lond.

AND

ALLEN PIGGOT, M R C S, L R C P.

Haemopneumothorax is not a common condition. The majority of cases follow trauma either in military or civil life, but the spontaneous form is distinctly rare After a close scrutiny of the literature of the past thirty years we have only been able to find eight recorded cases of which five occurred in this country Dr Newton Pitt[1] who recorded a case in 1900—almost identical with the case described below—stated that there is no reference to haemopneumothorax in the Index Catalogue of the United States Library, nor is it discussed in any of the standard treatises on medicine in either English, French, or German," and at that date he could find only one case in the literature unassociated with trauma Most modern textbooks make no mention of this condition, and no post-mortem examination of a spontaneous haemopneumothorax is to be found recorded since Newton Pitt and Sir Humphry Rolleston[2] reported two to the Clinical Society of London in 1930

The case described here is remarkable because of the rapidity with which the patient died, and the unusual findings post mortem.

The patient was a plumber, aged 44, who for at least the last nine years had complained of a winter cough, with an expectoration which had never contained blood. Associated with the cough, and persisting throughout the year, were attacks of pain referred to a point below the left clavicle. The pain had existed as long as the cough. The attacks came on at irregular intervals every few days, but were often of short duration. The intensity of the pain had been more severe for the past five years, and during the last three years the patient had noticed an increasing shortness of breath. He attributed his symptoms to muscular rheumatism, and as he had never consulted a doctor about them there is no record of previous investigations. Instead of the cough subsiding with the advent of warmer weather, this year it persisted, and since Christmas, 1930, the pain below the left shoulder had occasionally been sufficiently severe to disturb the man's sleep.

The patient was first seen on June 17th, 1931. The previous day he came home from work feeling quite well, but during the night, for half an hour, from 2.30 a.m., he had what he described as "a perfectly awful attack of coughing, when I seemed absolutely full of phlegm." There was some mucopurulent sputum, and he afterwards slept soundly till morning. He awoke with pain in his left pectoral muscles, but this worked off and he got up to go to work. Later the pain returned and he retired to bed again. He was a pale, thin-faced man, moderately well covered, and he demonstrated the position of the pain, as he sat in bed, over an area covering the pectoralis minor on the left side. His pulse, temperature, and respiration were normal. The chest showed some flattening over the apices, but movement on both sides was equal. The percussion note was unimpaired, and the heart appeared to be normal. No abnormality was found to account for the pain. As the pain eased he got up at midday, but returned to bed again at 8.30 p.m., complaining of pain in the same position. That night he slept well.

The following day, June 18th, he went to work but returned home because of pain. This subsided about midday, and apart from some cough he appeared quite well and pottered about in his garden in the evening. He again had a good night.

On June 19th he resumed work, feeling no pain, but returned home about midday because the pain had become severe, and went to bed at 3.30 p.m. Apart from the pain he felt well until 8.30 p.m., when he got out of bed to evacuate his bowels. Following defaecation the pain became intense, and he suddenly became faint and would have fallen if his wife had not saved him. He was examined again at 9 p.m. The pain had become very severe, and had spread over the whole of the left side of his chest. He also complained of pain in the abdomen and left leg. He was obviously very ill. His face was sallow and anxious, and the skin was cold and clammy. Temperature subnormal, pulse 100, respirations 40. The movement and air entry on the left side were diminished, and the percussion note was more tympanitic on the left side than on the right, but definitely less resonant than the note over the stomach. Owing to the collapsed condition of the patient he was not moved. The rectus abdominis muscles were rigid, but in view of the respiration rate and the condition of shock, pneumothorax was suspected.

Seen again at 6 a.m. on June 20th, his temperature was still subnormal, the pulse rate 120, very weak and thready. Respirations were still 40. The cardiac dullness was obliterated, and the percussion note over the left chest was definitely tympanitic, except at the extreme base, where it was dull up to the eighth rib, indicating the presence of fluid. The chest showed no bulging on this side, and a distant respiratory murmur was still audible. He was examined at 9 a.m. with Dr. H. Campbell Ferguson, who made the observation that the appearance of the man suggested an internal haemorrhage, and this, together with signs of air and fluid in the left chest, suggested the rare but probable diagnosis of spontaneous haemopneumothorax.

At 12.30 p.m. there was no cardiac dullness present to the left of the sternum. The percussion note over the whole of the left chest was tympanitic as far out as the axillary border. Outside this point it became dull, the dullness shifting and becoming replaced by hyper-resonance on the patient being turned towards the right side. No bruit d'airain could be demonstrated. A very faint respiratory murmur could still be heard. From this time on, the patient gradually sank, showing all the signs of internal haemorrhage, and died at 7 p.m.

Post-mortem Examination

On the abdomen and thorax being opened the left dome of the diaphragm was seen to be bulging down into the abdomen. The left pleural sac contained air and blood in considerable quantity (two pints), much of which was clotted. The heart and mediastinum were displaced to the right. The left lung was completely collapsed.

On removal the left lung was found to be entirely airless, and showed a small puckered tuberculous scar at the apex. There were also present near the apex two subpleural blebs. These apical blebs intercommunicated and opened out into a small, thin-walled, smooth cavity. There was no caseous matter present in the cavity, and it appeared to be formed by the coalescence of many emphysematous dilatations. Attached to the apex of the lung, one of them to the emphysematous blebs, were two firm, cordlike adhesions, which appeared to have been torn away from the chest wall before death. On section the lung tissue appeared to be normal. There was no blood present either in the trachea or bronchi, and but scanty secretion. Careful search failed to reveal in the lung the site of its rupture or of the haemorrhage.

The right lung showed some general emphysema. At the apex was a scar adherent to the chest wall, and in the centre of the scar was a small calcareous nodule. Around the apical scar were several emphysematous blebs similar to those in the left lung. The heart, aorta, liver, kidneys, spleen, and oesophagus were all quite normal in appearance.

Discussion

The chief interest of this case lies in the cause of the rupture of the lung and of the haemorrhage.

Of the eight previous cases mentioned six appear to have recovered. Two cases reported by G. A. Allan[3] in 1925 were confirmed by *x* rays to be due to tuberculosis. Others reported by R. B. Ness and G. A. Allan[4] (1910), R. Doria[5] (1928), L. M. Hurxthal[6] (1928), and A. H. Terry[7] (1930), were all of uncertain etiology. Of those which were examined post mortem, one mentioned by Newton Pitt[1] revealed a large phthisical cavity with an eroded branch of the pulmonary artery running through it. At the post mortem of Rolleston's case no air was found in the pleural cavity although it was present during life, and after a minute examination the origin of the blood remained in doubt. The post-mortem findings in Newton Pitt's[1] own case were not unlike those in the present one. An emphysematous bulla, about half an inch across, with an imperfect wall, was found, attached to which was a fibrous band that had been torn across. No obviously patent vessel could be seen, but the adhesion was suggested as a probable source of the bleeding.

In the case described by us the necropsy revealed the presence of a firm pleural adhesion attached to an emphysematous cavity at the apex of the left lung. The adhesion appeared to have been torn away from the chest wall during life, and it seems quite possible that it was from the torn adhesion that bleeding took place. In support of this contention we would mention a case reported by Krause and Heise[8] in which a man undergoing artificial pneumothorax treatment died of haemothorax due to a torn pleural adhesion.

The rapid death of the patient made further clinical investigations impossible, but in the absence of any other cause we are inclined to the view that the abnormalities found in the lung post mortem indicated the source both of the pneumothorax and of the haemorrhage, and that the strain caused by the violent attack of coughing during

the night of June 17th, and again by defaecation on June 19th, played a part in the production of the spontaneous haemopneumothorax.

We wish to thank Dr. H. Campbell Ferguson for helpful suggestions in connexion with this case.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

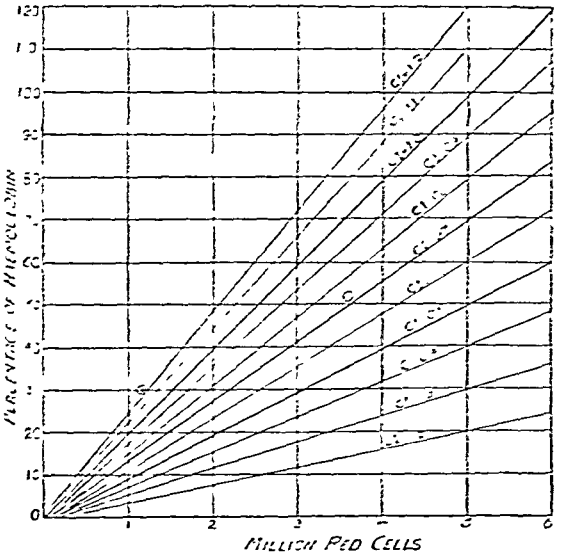
ABDOMINAL MANIFESTATIONS IN RHEUMATISM

The article by Dr. K. H. Tallerman on abdominal manifestations in rheumatism (*British Medical Journal*, November 7th, p. 844) tempts me to report a case at present under my care.

On September 22nd a boy, aged 8, complained of severe headache, sore throat, and pain in the abdomen, left shoulder, and back of the legs. He was sick once, and his tongue was heavily furred. There was general abdominal tenderness, but no rigidity. The temperature was 102°; a few moist sounds were present in the chest, but disappeared after a few days.

He passed green stools once or twice a day during the first week, after which they became normal in colour, but constipated. The temperature remained between 101° and 102° until October 2nd, then fell by lysis. After the first week he ceased to complain of any pain except headache, which lasted a further week. There was no swelling of any joint, no rheumatic nodules or enlarged glands were noticed. The persistent headache, with slightly distended tender abdomen and a relatively slow pulse, suggested typhoid fever, but a Widal test on October 2nd was negative.

By October 21st the temperature was normal, and the child was eating and sleeping well. On October 29th he again complained of pain and stiffness in the left shoulder. The temperature was 100°, and there was no sore throat. The pain had disappeared and the temperature returned to normal by November 2nd. No abnormality has been found in the heart throughout. He has had diphtheria twice, once very severely, otherwise he has had no serious illness. He has occasionally complained of "growing pains" during the last three years. There is a strong family history of rheumatism.



Dr. Tallerman's cases strengthen my suspicion that this child's illness has been rheumatic in origin.

RAPID METHOD OF WORKING OUT COLOUR INDEX

The present interest in microcytic anaemia prompts me to publish a chart which I made some years ago for determining the colour index, in order to avoid the usual calculation. Along the ordinate is marked the percentage of haemoglobin, and on the abscissa the number of red cells. A straight line is drawn from zero to the point of intersection of RC = 5 million with Hb = 100 per cent.; every point on this line represents CI = 1.0; thus, if there are 3·5 million red cells and 70 per cent. haemoglobin, a glance at the diagram shows the intersection of these lines to lie on the CI = 1·0 line. Another straight line is drawn from zero to the point RC = 5 millions, Hb = 50 per cent., every point on this line represents CI = 0.5; for example —2 million red cells and 20 per cent. haemoglobin lies on this line, so the CI in this case is 0.5. Other lines are drawn from zero to points above the RC = 5 million mark, each line representing CI = 0.1, 0.2, 0.3, and so on.

As examples: if RC = 3·6 millions and Hb = 52 per cent., the point of intersection will be seen to be just

above the CI = 0.7 line; by calculation CI = 0.72. Again, if RC = 1.2 millions and Hb = 30 per cent., the intersection is just above the CI = 1·2 line, by calculation CI = 1.25.

For accuracy the diagram should be drawn six inches square.

Westgate-on-Sea. — FREWEN MOOR, M.A., M.D.

CARCINOMA IN A LONG BONE SECONDARY TO CARCINOMA OF RECTUM

This condition must, I think, be exceedingly rare, and I therefore report the following case.

The patient, a man aged 69, had a colostomy performed for carcinoma of the rectum in December, 1928, and in the following February the growth was excised. In August, 1930, a swelling commenced on the left tibia, about the junction of the upper and middle third. As the growth gradually enlarged the pain increased, and the skin over it became tense and discoloured. The growth was of firm consistency, but not bony hard. The Wassermann reaction was negative.

Diagnosis of secondary carcinoma was made, but in view of the extreme rarity of this condition the possibility of an osteosarcoma could not be overlooked.

Report of X-Ray Examination.—The compact bone of the tibia below the superficial swelling shows destruction without any defined outline. Extending beyond the surface of the tibia into the swelling, there is an irregular and ill-defined shadow of bony structure. The appearances indicate a secondary carcinoma involving the tibia.

In March, 1931, the leg was amputated, and the pathological report of the tumour was as follows. Sections show a mass of very fibrous tissue in which are areas of haemorrhage, and scattered throughout are areas of osseous tissue. Interspersed among the osseous tissue are masses of very definite columnar-celled glandular tissue resembling that seen in a columnar-cell carcinoma of the rectum. The condition is undoubtedly a secondary deposit of a columnar cell carcinoma in the shaft of the tibia.

My thanks are due to Drs. Greller and Barlow, radiologist and pathologist respectively, for the care and interest taken in their investigations, and for the above reports of this case.

STANLEY J. FIPPIN, M.B., M.R.C.S., D.P.H.
Medical Officer, Hammersmith Hospital.

Reports of Societies

THE FITTING OF CONTACT GLASSES

At the meeting of the Section of Ophthalmology of the Royal Society of Medicine on November 13th, Mr. E. W. BREWERTON presiding, a short paper was given by Mr. RUGG-GUNN on the fitting of contact glasses.

Mr. Rugg-Gunn said that, looked at superficially, the fitting of contact glasses seemed fairly simple, and fortunately in many cases this was so. There was, however, a considerable residuum of cases in which difficulty was experienced in acquiring tolerance. The manner of fitting which he employed had been gradually evolved for himself, but it was identical, or practically so, with that at various Continental clinics. The determination of an exact scleral fit was of first importance. The fine determination of the scleral curvature ultimately prescribed must be done without the aid of any anaesthetic. The ideal plan was to fit the contact glasses provisionally selected in the morning, and to ask the patient to return in the afternoon, after a few hours' wear, before making a final decision. The average radius of curvature of the adult sclera was about 12 mm., and the great majority of eyes took scleral brims of 11.5 to 12.5 mm. The scleral brim was a section of a sphere cut parallel to its equator, and its mean diameter varied in size according to whether the cut was nearer the equator or the pole. Thus a section which fitted perfectly one eye with a rather small cornea would fail to fit a similar eye in which the corneal diameter was larger. This difficulty was not adequately met by applying a glass of slightly larger radius, though at present that was the only method of overcoming it in the case of Zeiss glasses. Uncertainty with regard to these measurements at present constituted a very real obstacle in the way of adequate comfort. Cases of high myopia were most difficult to fit, possibly because the length of the eye by increased leverage tended to flick off the glass. For high myopes a wider scleral brim, giving a broader zone of contact, would be an improvement. Turning to the corneal part of the contour glass, Mr. Rugg-Gunn said that it seemed best to divide the corneal series into two groups: (1) those of small curvature, which came into contact with the cornea only at the margin of the crown, and (2) those of larger curvature, which might come in contact with the cornea in the neighbourhood of its centre. Glasses from either of these groups would cause discomfort and possibly injury to the cornea; he had never seen anything in the way of abrasion, but he had seen corneal oedema, and had known of cases where patients had complained of dimness of vision and of haloes around lights after a few hours' wear. His experience with patients with conical cornea suggested that observations with the aid of fluorescein were indispensable in this condition. Contact near the limbus was better tolerated than contact near the centre. Cefact in the pupillary area of the cornea was very badly borne. Contact in the intermediate zones was least painful at the periphery, and became more painful the nearer it approached to the corneal centre. The principle of choosing, not the contour glass which gave the best visual result, but the one approximating to the nature of the cornea itself, and superimposing a spherical correction on its outer surface, must be observed in the interests of comfort. Mr. Rugg-Gunn added that in his opinion the practice which had arisen amongst a certain number of dispensing opticians of undertaking the fitting of contour glasses themselves was to be deplored. Many opticians now possessed sets of trial contour glasses, some of them very complete ones, which they lent or hired to ophthalmic surgeons who wished to use them. That was perfectly legitimate, for at the present rate of exchange a full set of Zeiss trial contour glasses cost something like £260, and could hardly be considered part of an ophthalmic surgeon's equipment. But the actual fitting should always be in the hands of the ophthalmic surgeon.

The PRESIDENT said that the Section owed a debt to Mr. Rugg-Gunn for the very clever work he had lately done on this subject. With regard to measuring the distance between a lens in a trial frame and the contact glass, when the patient had the contact glass on, one could actually put one's lens in contact with the glass, or almost so. The simplest plan when the contact glass was in position was to do a retinoscopy on the patient.

USE OF ANTISEPTICS IN THE CONJUNCTIVAL SAC

At the same meeting Mr. F. RIDLEY described some experimental work to determine the value of various antiseptics in the conjunctival sac. The problem was whether the antiseptic would destroy the organisms present before it was rendered ineffective by dilution in tears, or for what subsequent period it would inhibit the growth of organisms, taking into consideration the further dilution, and, moreover, whether the antiseptic was more destructive to the natural protective agent in the tears than it was to the organisms present. The first experiment related to fluorescein, and showed that even in the normal eye, with the minimum of irritation, the fluorescein which could be introduced into the conjunctival sac was diluted thirty-two times in eleven minutes. With this substance the dilution did not proceed in geometrical progression, whereas this principle did apply with other substances. With argyrol, for example, one-fifth became one-tenth in about forty seconds, and one-tenth became one-twentieth in the same interval. Mr. Ridley showed the results obtained with a number of substances in common use in the eye, stating the maximum dilution to kill the staphylococcus or streptococcus in fifteen minutes in 10 per cent. serum at 34° C. From these experiments it appeared that zinc sulphate in 1 per cent. strength had no killing power, but would inhibit down to a dilution of 1 in 600, and the same was true of many other substances. The most effective substance proved to be silver nitrate; 10 per cent. silver nitrate would kill down to a dilution of 1 in 1,000 and inhibit down to 1 in 25,000 or even 1 in 50,000. Only the results on staphylococci and streptococci had been tested, and, of course, it was unjustifiable to apply the results to other organisms. The question was simply whether the antiseptic in the time available destroyed the organisms present before it was diluted by tears. Only silver nitrate, among some twenty substances tried, survived this test. It was usual to ascribe the beneficial action of silver nitrate to the desquamation it produced, but it was none the less a very efficient germicide. Argyrol and protargol might exert an inhibiting action for a quarter of an hour, but silver nitrate in the eye might fairly be assumed to exert a powerful inhibiting action. As to the effect of these substances on the natural protective agent in the tears, silver nitrate destroyed it in high solution, but a concentration of 1 in 25,000 silver nitrate which was actively inhibitory to the organisms, did not affect the bactericidal power of the tears. He concluded that silver nitrate, argyrol, and protargol were the only effective antiseptics in this connexion, and of these silver nitrate was the most efficient, and might be used, he thought, with benefit in solutions weaker than the commonly employed.

The PRESIDENT said that he was glad to hear that the old-fashioned remedy, silver nitrate, was still useful. He was strongly in favour of very weak silver nitrate. He himself constantly painting lids with silver nitrate solution, and thought it useful.

Sir ARNOLD LAWSON said that he hoped to try silver nitrate in solutions of 1 in 100, and see what happened in very weak

He himself had been most interested in flavine, which he regarded as an inhibitor. He did not think flavine was of any use once there was a state of active infection, when, indeed, all these things were perfectly useless; but when it was desired to inhibit or prevent something coming which had not yet come, then flavine had its uses. Mr. M. S. Mayou said that the staphylococcus was frequently found on taking cultures from the conjunctival sac before doing a cataract operation. But the various parts of the conjunctiva did not show an equal distribution of organisms. The upper fornix, he thought, was practically always sterile. More colonies came from the lower conjunctival sac. Generally sections were made upwards, and that was the reason why cases did not go septic more frequently.

ANAESTHETICS FOR DIATHERMY AND ENDOSCOPY

At the first meeting of the Section of Anaesthetics of the Royal Society of Medicine, held on November 6th, with the president, Mr. G. Ramsey Phillips, in the chair, a discussion on anaesthesia for diathermy and endoscopy was opened by Dr. H. W. Featherstone.

Dr. Featherstone said that of recent years two of the more important developments in surgical technique were the use of high-frequency currents for cutting or burning tissue, and the examination of cavities and viscera of the body by illumination with electric lamps. These brought certain risks when they were employed in operations on the lungs and air passages and in the neighbourhood of the mouth. Chloroform, or a local anaesthetic alone, was often employed; but the former was not always advisable, and local anaesthesia might not be practicable. Chloroform did not burn, even in an oxygen atmosphere, but if heated strongly it disintegrated; the product, phosgene, was highly poisonous, and other resultants were irritating to the mucous membrane. Under ether anaesthesia it might become necessary to employ diathermy, and the anaesthetist must be aware of the main facts as to the possibility of explosions. In a case in Canada, attended with fatal results, the patient was given ethylene and oxygen for a pharyngeal operation. Diathermy became necessary, the ethylene was stopped, and nitrous oxide and oxygen were given for some minutes. After the diathermy had been applied for a few minutes an explosion occurred and fatally injured the patient. It was held to have been due to some of the ethylene-oxygen having been swallowed and regurgitated later. Dr. Lundy of the Mayo Clinic had stated that in 39,000 administrations in that clinic there had been no explosion. Sometimes the blowing of ether and oxygen into the pharynx had resulted in explosion. Ether-oxygen mixture could be ignited at a temperature of 190° C. It was a common practice for anaesthetists to use an apparatus which permitted administration of ether and air or of ether and oxygen at the beginning of the operation, changing to chloroform or chloroform and oxygen a few minutes before an electric lamp or a diathermy apparatus was to be used. This was the procedure in the recent case at a Birmingham hospital in which the patient received fatal injuries. Post mortem there were found extensive bruising of the pharyngeal mucous membrane and a ragged tear in the mucous membrane of the pyriform fossa. There was intense inflammation of the bronchial tree. The first explosion occurred in the mouth, and was transmitted along the rubber tube to the anaesthetic apparatus. A defective control between lamp and holder resulting in a spark started the trouble. Ethylene-oxygen should never be used in conjunction with any form of electrical appliance. There was a high range of explosibility, between 2 and 20 per cent. Large quantities of ethylene might be liberated in an operating theatre. Ethylene explosions were very powerful. The ether-air mixture delivered into the trachea from an endotracheal apparatus, if rich enough to maintain anaesthesia, could always be ignited, and this should be remembered when diathermy of the lung was to take place.

Was the exhaled air and ether mixture from the lungs of a deeply anaesthetized patient combustible? A spark or flame had been applied to (1) specimens of expired air and ether collected immediately after the withdrawal of a heavily impregnated ether mask; (2) to collected expirations during deep ether anaesthesia; and (3) to a mixture exhaled directly after deep inspiration of a strong ether-air mixture. None of these specimens could be ignited. This accounted for the rarity of serious damage to patients in whose mouths a mild explosion or burst of flame had occurred during intrapharyngeal administration of ether and air. Hence it seemed safe to apply diathermy in the mouth of a patient who had been given ether, provided (1) that the patient took a dozen breaths of fresh air following discontinuance of the ether before the diathermy was applied, and (2) that care was taken that the stomach was not distended with ether vapour and air swallowed during induction. Nitrous oxide was not in itself a combustible gas. The administration of a basal narcotic permitted the use of gas-oxygen or a light chloroform anaesthesia, or even of no anaesthetic at all during diathermy or endoscopy.

J. D. Morgan, D.Sc., said that most gases supported combustion only when united with air or oxygen within certain proportions. If a mixture of maximum inflammability was ignited in a glass tube the flame moved rapidly through the whole tube. Either a richer or a weaker mixture would burn less rapidly, but the flame would not be extinguished till it had passed through the whole tube. The lower limit for ether-air was about 2 per cent.; the upper limit seemed incapable of precise measurement. The lower limit of ether-oxygen was less than 2 per cent. In ether-oxygen, increase of the oxygen content increased the ignitibility of the mixture. An ether-air mixture of strength sufficient for anaesthesia would stand a large spark without exploding, but the same spark would readily ignite a mixture of the same proportions of ether and oxygen. He emphasized the relatively low ignition temperature of ether-air and ether-oxygen mixtures. Liquid ether, when containing impurities, might ignite at a temperature as low as that of boiling water. It was very important for anaesthetists to know that ether-oxygen mixture would ignite more readily than ether-air. When ether and oxygen were combined in a maximum inflammability mixture the greatest danger existed, and the slightest spark would cause ignition. He had found that the mixture of ether obtained when air or oxygen was passed through the chloroform bottle of a Shipway apparatus was one approaching maximum inflammability. The outlet of the ether bottle was always open to the delivery pipe, and ether vapour was free to pass to the delivery tube by either diffusion or suction. The danger was increased when warm water was placed round the ether bottle; conversely, the danger might be absent when the ether was very cold. Dr. Morgan said that he had arrived at two conclusions: (1) no electrical apparatus of any kind capable of giving a free spark or exposing a hot surface should be put into the mouth of a patient while ether-air, and especially ether-oxygen, was being administered; (2) the Shipway apparatus, when employed in operations where risk of ignition occurred, should be fitted with a cock which closed the outlet from the ether bottle when air or oxygen was diverted to the chloroform bottle. He exhibited a pencil light and a cock devised to obviate the kind of risks which preceded the Birmingham explosion.

Mr. MUSGRAVE WOODMAN said that, however bad the patient might be, oxygen should never be used when a lamp was placed in the mouth. He did not rely on switching on chloroform after ether, but inserted the lamp the moment the anaesthetist stopped, thus securing the richest mixture in the mouth and not waiting for inflammable dilution. Dr. C. F. HADFIELD drew attention to the valuable work on the subject which was done by the late Professor W. E. Dixon, and said the attitude of the anaesthetist should be one of excessive caution. The danger of a serious result was greater when the vapour was being given endotracheally. The use of the diathermy knife increased the range of danger, even if the spot at which it was applied was some distance from the anaesthetic. Even if the patient was surrounded by a towel, ether had been found capable of getting through or round the folds. Dr. KIRKBY THOMAS related an incident showing the low temperature at which ether vapour would explode. Dr. A. LOWNDES YATES spoke of the chance of aspirating apparatus for the removal of mucus from the nose becoming hot enough to cause an explosion. Explosions might be attributed to the lamp when it was not guilty. Mr. V. E. NEGUS said that if the suction pump was properly enclosed there was safety from explosion. The majority of endoscopic examinations could be carried out without a general anaesthetic, and for diathermy chloroform could be employed. Dr. [illegible]NGTON HEWER said he had carried out intubation under [illegible]er many times, and had never heard of an explosion [illegible] those circumstances. He referred to the possible risks of giving anaesthetics in a private room a few feet away from a fire.

The PRESIDENT reported a case of combustion in a gas-and-oxygen apparatus said to be due to the sudden liberation of oxygen at high pressure (1,750 lb. to the square inch) into the space between the bottle valve and the reducing valve. The heat produced by the sudden compression of the air between the two valves was sufficient, in the presence of oxygen, to ignite the material of which the valve was composed. He had been informed by the manufacturers of oxygen that appreciable quantities of ether were occasionally found in oxygen bottles returned for refilling. To reduce the former risk the reducing valve should always be opened first, and the bottle valve then turned on very gradually. To avoid the second, the oxygen valve should be turned off immediately the bottle was empty. Mr. HOWARTH spoke of the value of basal narcotics where inhalation anaesthesia involved explosive risks. He had carried out many operations of the kind with basal narcotics and no further anaesthetic.

INNERVATION OF THE BLOOD VESSELS

At the opening meeting of the Manchester Medical Society on October 7th the President, Professor J. S. B. STOPFORD, gave an address on the innervation of blood vessels.

After reference had been made to certain important facts regarding the histology of blood vessels, the speaker described the innervation of the vessels of the limbs by branches from two sources of supply—a proximal source from the sympathetic system, and a distal source from neighbouring peripheral nerves. The investigations made by Blair and his co-workers and Woollard were discussed, and consideration was given to the perivascular plexuses, and the source, distribution, and function of the different types of nerve fibres found in them. Special reference was made to the question of innervation of the capillaries, and the value of the histological and experimental evidence bearing upon this subject was critically analysed. Professor Stopford then went on to consider whether the blood vessels were sensitive. He pointed out that there was no anatomical support for the view that there was a sympathetic sensory path from the blood vessels, and indicated the fallacies in certain clinical observations which had been submitted in favour of this contention. After reference had been made to recent animal and human experiments in this connexion, he expressed the opinion that there was some reason for believing that some blood vessels might be sensitive, but that the sensory path in such case must be in the cerebro-spinal nerves. In conclusion, Professor Stopford presented the evidence from his own observations and those of Telford, which demonstrated that prolonged irritation of vasomotor fibres was liable to provoke serious changes in the walls of blood vessels; these were liable to be succeeded by thrombosis and vascular occlusion. He submitted a theory suggested by Telford and himself as to the way in which the vessels reacted to prolonged irritation of their vaso-constrictor fibres, and described the changes which occurred in the vessel wall.

CRIMINAL ABORTION

At a meeting of the London Association of the Medical Women's Federation on October 29th, with the president, Dr. LETITIA FAIRFIELD, in the chair, Sir BERNARD SPILSBURY read a paper on criminal abortion.

He said that the terms "abortion" and "miscarriage" referred to loss of the foetus before the sixth month; the term premature labour was used when the loss occurred after the sixth month. The act was only criminal when proof of intention was forthcoming—for example, when a medical man passed an instrument into the uterus of a woman whom he knew or suspected to be pregnant, he clearly showed his intention to procure miscarriage. He would be held guilty unless he could show some good and sufficient reason why pregnancy should be terminated prematurely in her case. The act which procured abortion might be capable of an innocent explanation—for example, following injection of fluid into the vagina, in the course of treatment for gonorrhoea. Only the absence of any disease which would justify such treatment would lead to suspicion of the practitioner's motives.

Criminal abortion might be: (1) self-induced—most often by general violence and drugs, but occasionally by local violence; or (2) induced by another—most often by drugs and local violence, seldom by general violence. General violence was commonly the first attempt at self-induction. Methods used were excessive exercise, tight lacing, lifting heavy articles, very hot baths, jumping or falling from a height. Occasionally these methods were effective, notably in women who aborted easily, but they might result in death, or endanger life through injury. Local violence could be defined as any mechanical means employed upon the uterus or adjacent structures which either would stimulate the contraction of the uterine muscle directly, or, by damaging the ovum or detaching it from the uterus, would indirectly bring about the same result. The means included the passage or attempted passage of an instrument. The instrument used by a woman on herself might be a skewer, hatpin, knitting needle, hairpin, or crochet hook; abortionists used catheters, sounds, bougies, curettes, tents, or other dilators. The use of such instruments by an unskilled person required some anatomical knowledge, and malposition of the uterus might foil such attempts. In many cases when instruments were used by a skilled person no injury resulted, though undue haste, or the intemperate habits common in professional abortionists, sometimes caused them to make mistakes. Possible dangers were: sudden stretching of the cervix, causing a tear; sudden overcoming of the resistance at

the internal os leading to penetration of uterine wall or injury to placenta; malposition of uterus; and an abnormally placed placenta. Non-instrumental methods included injections into the vagina, which might be self-administered, or intrauterine injections, which were nearly always administered by skilled abortionists. These included watery fluids which might contain antiseptics, or a soap solution. Other methods were blowing air into the uterus; manipulation of the external os; packing the vagina; massage of the uterus through the abdominal wall; passage of electric current through the uterus; dilatation of the cervix and removal of the contents of the uterus with a curette. The dangers of local violence were septic infection, haemorrhage (which might be internal if perforation had occurred), and shock. Infection in the early stage was limited to the uterus and adnexa. The bold surgical policy of removing the uterus completely was more likely to save life than more conservative methods. The risk of shock could not be anticipated; and death from it sometimes occurred in the most unexpected cases at the moment when an instrument was passed into the uterus. Fatal shock might follow the sudden distension of the uterus by injection of fluid, or the sudden stretching of the cervical canal.

In discussing abortion induced by drugs, Sir Bernard Spilsbury quoted a statement by Dr. F. J. Smith, that there was no drug or combination of drugs which would, when taken by the mouth, cause a healthy uterus to empty itself, unless it were given in doses sufficiently large seriously to endanger, by poisoning, the woman's life. It was in women with whom miscarriage normally happened with little provocation that abortion was procured easily with drugs.

It was often difficult for a practitioner called to a case of abortion to know whether or not the abortion had been induced, unless the circumstances excited suspicion. Sometimes the patient invented an accident, such as a severe fall, or a blow upon the abdomen, to explain the miscarriage; thus the association of cause and effect between an accident and miscarriage might be less frequent than was usually supposed. The patient rarely took the doctor into her confidence, and, faced only with symptoms of a secondary infection, he might never suspect that he was dealing with a septic abortion, especially if called in only some time after the abortion had taken place. It was therefore a reasonable assumption that criminal abortion was more frequent than was generally suspected, and the evidence obtained in many criminal cases of the long career of the abortionist, and the large number of cases that had been treated by him before detection, supported that view. A useful pointer to diagnosis was the time-relation to the miscarriage of a febrile infection traceable to an infection of the genital tract. If an interval of time followed the miscarriage before the symptoms and signs of infection appeared, then the infection was likely to have occurred as a *complication* of the miscarriage. If the infection occurred either before, during, or immediately after a miscarriage, then there was some ground for suspecting that it had been procured by some means of local interference.

In the course of the discussion, Mrs. IVENS KNOWLES confirmed, from her own experience, the good results of complete removal of the uterus in septic cases. The PRESIDENT commented on the deductions to be drawn from the risks that Sir Bernard Spilsbury had described—that some degree of sepsis followed many cases of abortion which were never discovered, because the woman survived, and that much disability and ill-health in after life might be attributable to this cause. Sir BERNARD agreed, and said that the greatest factors in producing sepsis were the haste and secrecy in which criminal abortion had to be performed.

MEDICAL SERVICES IN A FUTURE WAR

A brief but interesting discussion took place at the Royal United Service Institution on November 4th, following a paper by Major G. Wilson, R.A.M.C., on "The Army Medical Services in a future war."

Major WILSON in his review stressed the importance of peace-time training for war, incidentally making it clear that, in so far as the medical services were concerned at the present moment, the training left much to be desired; he stressed the importance, also, of liaison between the medical services and the combatant branches, which is in some danger of diminishing, and he paid a tribute to the science of hygiene and what it had done for the Army in the past. With regard to the collection of wounded, he referred to a topic on which there had been a good deal of discussion—namely, the arrangements for the collection of wounded from tanks, and also the use of the aeroplane. Another point was that casualty clearing stations, in his opinion, should be given a greater mobility, or that one part of the casualty clearing station might be sent forward to reduce the number of uncomfortable journeys which had to be contemplated when long distances intervened.

Major-General J. A. HARTIGAN said that the importance of peace-time training in the medical services was well realized by their officers. He was constantly being asked for field medical units, either complete or in skeleton, but as a rule he had to say that, owing to the temporary shortage of officers, and to the fact that the establishment of other ranks was cut down to the bare minimum required to run the routine duties of a station, it was impossible to take any part in manœuvres and exercises. In consequence, medical officers had very little chance of acquiring practical knowledge of the tactical handling of units in the field, and—what was equally important—commanders and staffs of formations had no opportunity of learning the functions and organization of those units. In view of the fact that the collection and disposal of his casualties was by no means the least of the anxieties of the commander in the field, it seemed to General Hartigan a great pity that that problem was entirely overlooked in ninety-nine exercises out of a hundred carried out in the Army to-day, and for that reason the exercises and manœuvres lost much of their practical value. With regard to the disposal of casualties by aeroplane, he foresaw the time when this method of transport would come very much more into the picture. The changes which had lately taken place in military science were almost entirely in the direction of mechanization, the object of which was to increase mobility, and with this increased mobility, as he saw it, the difficulties of the medical services in the field would be increased to a very great degree, simply because the distance between the mobile medical units of a division and the immobile units would be enormously extended. In the aeroplane lay the greatest hope for dealing with this increased mobility, and in future armies, he suggested, the D.D.M.S. of a corps or an expeditionary force would have on its strength one or more fleets of aeroplanes for the evacuation of the wounded from the main dressing station to the railway.

Major-General P. H. HENDERSON supported General Hartigan's view about aerial ambulance, saying that on several occasions during the great war he had felt the need of such transport, and had asked for it without success. But he felt that unless the medical services stressed the need for a properly organized aerial medical service in peace time, the other branches of the Army would not rise to the necessity of it, and, should in the war break out, this essential would still be lacking. General Henderson also mentioned that from his experience he had felt that the wounded were unnecessarily

taken from the advanced dressing station to a main dressing station before being evacuated at the casualty clearing station. The essential thing was to get the wounded man from the battlefield to a hospital at the earliest possible moment, so that he could receive not only adequate treatment, but adequate rest after treatment. With the more rapid means of transport available, the main dressing station might in many cases be eliminated. The statistics which it was customary to collect there could quite well be obtained by attaching one or two clerks from the field ambulance to the casualty clearing station to which the wounded were going, and passing on the information to the division concerned.

Major WILSON, in replying to a question as to co-ordination with the Royal Air Force, said that as things stood at present, the regulations governed co-ordination between the Air Force and the Army to this extent—that all casualties from the Air Force in war time, where the Air Force was functioning with the Army, were dealt with by the Army medical organization, but the Air Force had the responsibility of collecting these casualties and transporting them to the nearest Army medical unit. No difficulty was anticipated in a future war in maintaining a co-operation with the Air Force.

Lieut.-General Sir HAROLD FAWCUS, D.G.A.M.S., who presided, remarked that it seemed to all R.A.M.C. officers that enough prominence was not given, and never had been given, to medical problems on staff exercise. Staff exercise in higher formations really did not go beyond Corps formations, and hardly touched the Divisions, whereas the main operation of medical interest was the evacuation of wounded in the divisional area.

CARDIOSPASM

At a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, on October 30th, with the president, Mr. R. ATKINSON STONEY, in the chair, Sir WILLIAM WHEELER showed a case of cardiospasm or achalasia after operation.

The patient, a man aged 42, gave a history of dysphagia for twenty-three years. In 1913 he was treated for four months by the passage of bougies, and he was dilated with a hydrostatic bag in 1929. When seen four months previously he had been losing weight. He vomited after every meal, fluids being as difficult to swallow as solids, but there was no epigastric pain. There was no hydrochloric acid in the regurgitated food, the blood picture was normal, and the faeces contained no occult blood. The patient's age, the length of history, and the nature of the vomited material made the diagnosis of achalasia possible before *x*-ray photographs were taken; these revealed intermittent obstruction at the cardia, and enormous dilatation of the oesophagus. One month after the operation *x* rays showed very little obstruction at the cardia, but the oesophagus was markedly dilated. A month later there was very great improvement, as seen both by screening and by photographs. Thick fluid emulsion passed easily through the cardia, and the dilatation of the oesophagus was greatly reduced. Four months after the operation, however, the passage of barium was not quite so free as on the previous occasion. A few days after the operation the patient appeared clinically well. He was able to eat all kinds of food, and in three months his weight had increased by two stone.

Sir William Wheeler emphasized the fact that it was wise to wash the oesophagus out for several days before an operation; otherwise, when the cardia was dilated by the retrograde method, the field might become flooded with foul oesophageal contents.

He also drew attention to Walton's observation that at each respiration the cavity of the oesophagus opened and closed, the air being audibly sucked in and out. The patient had "oesophageal respiration." At the commencement of the operation a tube was passed, and the sucking in and out gave the false impression that it had been passed into the trachea. The possible causes of achalasia were discussed, and the case was compared with one of Hirschsprung's disease, which had been recently operated upon successfully, by removal of the sympathetic plexus controlling the pelvi-rectal sphincter. In the treatment of these cases, Sir William Wheeler recommended conservative treatment along the lines advised by Hurst (the passage of a mercury tube), or dilatation with a hydrostatic bag after the method of Plummer. He believed, however, that there were many cases in which conservative treatment could not be employed with success. Retrograde dilatation of the cardia with the fingers through an opening in the stomach had been almost universally successful. Before operating, it was wise to have a silk thread or small bougie passed into the stomach, since it might be difficult to locate the cardia when the stomach was opened. In the present case, no obstruction was felt at the operation. The cardia was easily dilated with three fingers, and there did not appear to be any abnormality or tightening at the diaphragmatic opening, a condition which had been observed by some authorities.

Dr. T. GARRATT HARDMAN demonstrated lantern slides, showing the radiographic appearances of the case before and after operation. The PRESIDENT mentioned a case of achalasia in a woman, aged about 40, seen three years previously, which was relieved by palliative methods. He quoted a paper by Plummer, in which it was stated that every patient could swallow thread, provided the right type of thread was given in the right way. Mr. A. A. MCCONNELL referred to the relative ease with which the fingers could be passed through the cardia, and said that it seemed extraordinary that an opening into which the fingers could be so readily passed could give rise to such marked obstruction.

PAROTID TUMOURS

The PRESIDENT showed a patient from whom a tumour of the left parotid gland had been removed some years before. After a year, however, the tumour recurred, and for the last three years had been increasing in size. It was now very large and hard, and spread backwards behind and underneath the ear; it was rather tender, but there was no sign of facial paralysis. The patient had had treatment by deep *x* rays, but Mr. Stoney doubted if this would do much good, except that it might decrease the size of the tumour and make operative removal possible. These tumours, he added, were usually classified as sarcoma, carcinoma, and mixed tumours; the last were more or less innocent in the early stages, but had a tendency to recur. The present case was almost certainly a mixed tumour, which was possibly undergoing malignant change.

Mr. A. B. CLERY mentioned five cases of parotid tumour, four of which were small and easily removed under local anaesthesia. In the fifth, which was larger, rapid recurrence took place. Dr. H. B. GOULDING said that it was formerly considered that such tumours were chondrified sarcomas, but the PRESIDENT, in reply, said that they were now thought to develop from endothelium. Mr. CLERY showed a child, aged 5, who had been extensively burned at the age of 18 months. The tip of the nose was drawn up to the eyebrows, as a result of contraction, necessitating a complicated rhinoplasty. He described by means of lantern slides the operative procedure adopted.

Mr. W. DOOLIN read an interesting and entertaining paper on "Some old journeymen surgeons," illustrated by lantern slides.

Reviews

CLINICAL CHEMISTRY

Quantitative Clinical Chemistry,[1] vol. i, *Interpretations*, by Professor J. P. Peters and Dr. D. D. Van Slyke, is the first half of an important textbook that has been prepared by these authors. The general scheme of the work is that each chapter treats of a single chemical substance, the biochemistry being first discussed and then the variations produced by disease. For example, the chapter on haemoglobin contains a description of the physical chemistry and biochemistry of haemoglobin, and this is followed by a discussion of such problems as anaemia, anoxia, cyanosis, carbon monoxide poisoning, and methaemoglobin. The volume therefore presents a full survey of pathological chemistry, together with a clear explanation of its relationship with normal biochemistry. The authors explain in their preface that the original intention was to write a textbook of pathological chemistry, but that they found it impossible to give an intelligible account of this subject without dealing at the same time with the normal biochemistry on which it must be based. They are to be congratulated on their decision, for in the past an enormous amount of time and energy has been wasted in the attempt to interpret pathological chemical changes without understanding the chemical processes that occur in normal individuals. There are numerous instances of complex chemical tests for disease, which were applied for years, but which were finally shown to be of little value, because most of the results that were assumed to indicate disease really fell within the limits of normal variation.

The scale of the work is one that deserves comment, containing as it does nearly 1,300 pages. Works of this size are commoner in German than in English, and are usually composed of a series of monographs of unequal value and poorly co-ordinated. This volume, however, presents a uniform review of the field of inquiry. One of the authors is a professor of clinical medicine, the other is a distinguished biochemist, and they have collaborated in all that has been written. In this way a fair balance has been maintained between the laboratory and the clinical aspects of the problem. They mention that the volume has been six years in preparation, and perusal of it shows that it has been put together with great care. Textbooks as large as this are apt to degenerate into a kind of synthesized card index which provides the readers with a brief summary of a series of conflicting opinions. Here the authors have given a clear and critical digest of the evidence. Their subject is a thoroughly difficult one, and the book cannot be considered easy reading, but it does give the reader a rational account of the present state of knowledge. In this regard it may be mentioned that the bibliography is very full, and that adequate attention has been paid to the literature of all languages. One specially valuable feature of the work is the excellent graphs.

A glance through this volume brings home the fact that the astonishing growth of biochemistry during the present century is now resulting in a remarkably rapid development of pathological chemistry. Unfortunately, the increase of knowledge is revealing very clearly the difficulties of the latter. The simplest system in biochemistry is much more complex than any that a physical chemist cares to work with, but pathological chemistry has to try to account for the manner in which these complex systems are deranged by disease. The frequent use of complex formulas to express and interpret results obtained in clinical chemistry is a feature that is comparatively new and unfamiliar in this subject, and may prove a trial to readers unfamiliar with the methods of physical chemistry. In general, the authors have produced an authoritative and comprehensive textbook which should advance the science of clinical chemistry. In the first place, they have provided a reliable guide to the literature; and in no science is this more needed than in clinical chemistry, for its development is so rapid that results often pass out of date almost as soon as they are published. Still more important, however, is the fact that they have made a serious effort to establish clinical chemistry on a firm scientific basis.

ABDOMINO-PELVIC DIAGNOSIS IN WOMEN

Dr. Arthur John Walscheid has presented an elaborate account of the clinical aspect of gynaecology in *Abdomino-Pelvic Diagnosis in Women*.[2] The book is offered to the post-graduate student, and the author's aim has been to give an advanced description of the symptomatology of this branch of medicine. He has limited himself to a description of symptoms and physical signs, omitting references to treatment and paying no great heed to pure pathology. It is a comprehensive work, and most methods of investigation are described in detail. Even such procedures as illuminating the bladder and rectum to diagnose cystocele and rectocele are referred to, and mention is made of utero-salpingography in the diagnosis of retrodisplacement. The most remarkable feature of the book, however, is its size compared with the information it contains. Most of the chapters could conveniently be reduced in length if the style adopted were more concise. The scheme which the author has followed of representing personal impressions merits respect, but it suffers from the grave disadvantage that these experiences are not usually supported by corroborative evidence from the literature. References are extremely scanty, and in a volume of these dimensions a fairly complete bibliography is essential.

Dr. Walscheid has endeavoured to build up his arguments on an anatomical basis. The modern tendency is to write clinical descriptive works upon a basis of pathology. A book of this scope can appeal only to gynaecologists, and it is extremely doubtful if their needs will be satisfied by a work which dismisses the pathological side so summarily. For example, there is a small section on gonorrhoeal metritis which gives no pathological evidence of the existence of this condition. It is improbable that many gynaecologists in this country would admit the existence of a metritis of gonococcal origin; consequently, in spite of the interesting clinical descriptions, this section gives an impression of unsoundness. Again, in the section dealing with dysmenorrhoea there is no accurate account of the pathology of this complaint, and the rare condition, nasal dysmenorrhoea, is over-emphasized. The illustrations are of a mixed quality. The diagrams and photographs of specimens are fairly good, but the photomicrographs are hardly up to the standard of recent productions from America.

Nevertheless, the book contains useful material, and any contribution which presents a mature experience with practical instruction is always to be welcomed. The section on special gynaecology, with its descriptions of the clinical aspects of new growths, is very valuable, and particular mention should be made of the admirable way in which diseases of the vulva and vagina have been treated. On the other hand, the subject of ovarian

[2] *Abdomino-Pelvic Diagnosis in Women*. By Arthur John Walscheid, M.D. London: H. Kimpton. 1931. (Pp. xviii + 1,099; 397 figures, 1 plate. 52s. 6d. net.)

tumours has been badly neglected, and the accounts that are here given hardly represent the importance of ovarian tumours in gynaecology; further accounts might have been given of uterine adenomyomata and of chocolate cysts of the ovary. It is doubtful if Dr. Walscheid's book will achieve popularity in this country. The style is foreign to that of our contributions, and it is not always easy to understand quite what the author means.

RENAL FUNCTION

A seven hundred page monograph, entitled *On the Principles of Renal Function*,[3] by EKEHORN, must be regarded as a definite contribution to renal literature. The weaknesses of many of our renal hypotheses are exposed, and the author has dealt with much of our existing knowledge of the kidney in an original way. His central theme is that, despite claims to the contrary, most of our present knowledge is only concerned with the function of the kidney as a whole, and reveals nothing of the separate parts played by the glomeruli and tubules. Occasionally his arguments are somewhat vague, but in the main they appear scientifically sound, and his stated opinion that certain types of experimental work cannot by their very nature yield information on the separate mechanisms of renal function is probably correct.

In the experimental section of this monograph the author writes for the man who would repeat his work, and therefore gives a detailed account of his technique. This section deals with the methods he has used in glomerular puncture, and the subsequent analysis of the minute amounts of fluid thereby obtained. Ekehorn's technique resembles that of Richards and his co-workers, but he has modified earlier methods and obtains even larger quantities of protein-free fluid from a single glomerulus. The technical difficulties in the collection, manipulation, and analysis of this fluid are so numerous that the possibility must still remain of some uncontrolled factor which, if known, would alter the significance or nature of the results. The author is fully aware of these difficulties, and consequently his deductions from this section of his work are cautious. In the section dealing with the "protein proof" of glomerular "filtration," in contradistinction to "secretion," his arguments appear less carefully thought out, and his inability to recognize obvious gaps in the chain of his deductions is disappointing even to those who are in entire agreement with his conclusions that the glomerulus is an ultra-filter. In the opinion of the reviewer the "protein proof" is not, as Ekehorn suggests, almost the only valid evidence of glomerular ultra-filtration, but is simply to be added to the heap of other inconclusive evidence.

Ekehorn's monograph is much to be commended for its clearness of outlook, and for an excellent summary of literature bearing on the essential problems of renal function. Of particular interest is his summary of the many studies on the frog. It has been claimed that ligature of the renal artery in these animals cuts off the entire blood supply of the glomeruli, and that substances appearing in the urine after renal-portal transfusion can therefore only be the result of tubular secretion. Ekehorn rightly gives prominence to Adami's paper, in which it was conclusively shown that in not one instance were all the glomeruli shut out from the circulation by the most careful ligature of the renal arteries. Ekehorn stresses also the fundamental importance of determining, if we can, the amount of fluid coming from the glomerulus. If the total amount of glomerular fluid is really large, then the relatively high concentration of some urinary constituents must be explained by simple resorption from the tubules. On the other hand, if the total amount of glomerular fluid is relatively small—two or even ten times the amount of the urine as finally excreted into the bladder—then both secretion and resorption must be assumed to explain the high concentration in which creatinine and urea appear in the urine and the low concentration of other substances relative to the blood plasma. Ekehorn gallantly tackles the work of Starling and Verney, and rightly so, since their papers represent one of the chief difficulties confronting supporters of pure filtration-resorption hypotheses.

A COMPENDIUM OF HAEMATOLOGY

Compendium is a good name for an interesting collection of facts and discussions about the blood in its association with a dominant reticulo-endothelial system by Professor FELIPE JIMÉNEZ DE ASÚA.[4] Unlike most books on haematology, it is in no sense for laboratory use or for junior students. Descriptions of routine methods of examination are omitted, the normal function of the blood is barely mentioned, and the meaning of the amount of haemoglobin present in the blood, how it is estimated and how it varies, seems to be of less interest than the degree of resistance of the red cells to saline solutions. The volume of the blood and the application of its variations to clinical medicine are not referred to. The author introduces his subject with a description of the reticulo-endothelial system, in which he includes an account of the vascular distribution in the spleen and its relation to the circulation and reticulo-endothelial system of the liver, and discusses the parts played by the spleen and liver in the destruction and regeneration of blood cells, together with the fate of haemoglobin and the vexed question of the source of bilirubin. A further section deals with the relation of the haemopoietic apparatus and the reticulo-endothelial system to immunity and the production of antibodies. In his account of the histology and development of blood cells the various schools of unitarismus and dualismus are described, but the author makes no personal statement of his views on these much-debated theories. The classification and description of the various types of anaemia and leukaemia are well set out, with short notes on the treatment of these diseases. Dealing with the liver treatment of pernicious anaemia, no mention is made of the "reticulocyte response," now regarded as of first importance in the treatment, prognosis, and diagnosis of this disease; nor is there any reference to treatment by stomach extract. These and other omissions may possibly be explained by the fact that the book is dated 1929. Discussions on sprue, sickle-cell anaemia, and familial acholuric jaundice would have been welcomed. In spite of its omissions this is an enjoyable book to read. It would be much improved by a good index and a stronger binding.

ADDISON'S DISEASE

The clinical wealth of the Mayo Clinic has enabled Drs. L. G. ROWNTREE and A. M. SNELL to analyse no fewer than 108 cases, and has thus provided opportunities for improving the unsatisfactory treatment of this comparatively rare disease. In their recent monograph, *A Clinical Study of Addison's Disease*,[5] they first sketch the knowledge of the adrenal glands from their discovery in the sixteenth century up to the publication of Addison's original and classical account of "The Constitutional and

[4] *Compendio de Haematologia.* Por Felipe Jiménez de Asúa. Cordoba (Rep. Arg.): Imprenta de la Universidad Nacional. (Pp. 302; 58 figures.)

[5] *A Clinical Study of Addison's Disease.* By Leonard G. Rowntree, M.D., and Albert M. Snell, M.D. Mayo Clinic Monographs. Philadelphia and London: W. B. Saunders Company. 1931. (Pp. 317; 41 figures. 18s. net.)

local Effects of Disease of the Suprarenal Capsules" in 1855, which is here reproduced in full on account of its great historical value and its relative inaccessibility. Whereas Osler had only seventeen cases of Addison's disease, 33 [illegible] published hospital and consulting practice in America [illegible] at the 108 Mayo Clinic cases have come to necropsy [illegible] this represents the experience of twenty-two years' [illegible] which 696,789 patients registered at the clinic—an incidence of 1 in 6,450. Two methods of treatment have been employed by the authors; in 1926 the Murlin [illegible] of intensive treatment by adrenaline and adrenal [illegible] substance was started and given to fifty-seven [illegible] of whom thirty-two are recorded as having [illegible] and a sixth of the total were living after ten years. This treatment, named after a medical man [illegible] whom it was first tried, is compared with that of [illegible] and radium on carcinoma, which also commonly [illegible] temporary improvement. Since January, 1929, the hormone extracted from the adrenal cortex by Swingle and Pfiffner has been given by intravenous injection to nine patients, whose cases are fully reported. Though the present report is admittedly of a preliminary nature, the results point to a real advance in treatment, and, indeed, are compared in this respect to the use of insulin in the coma of diabetes mellitus. It is remarkable how, when given in a crisis of Addison's disease, it restores the patient to health within two to five days, banishing anorexia and increasing the appetite to the point of hunger, producing a feeling of well-being and a gain in body weight. This beneficial effect lasts about two weeks, and it appears that patients dying of Addison's disease fall short of good health through a lack of a little only of the cortical hormone. Unfortunately the supply of it is at present extremely limited, but steps are being taken to meet this need. In addition to the account of treatment the other aspects of the disease are fully described.

NOTES ON BOOKS

The first edition of Professor Rudolf Grashey's Atlas of Surgical and Pathological X-Ray Pictures[1] appeared in 1903, the second in 1924, and the third, improved and enlarged, was published last March. It is now a book of established reputation. The first part consists of a summarized text, beginning with the subject of foreign bodies and methods of detecting them and of localizing them, in relation to landmarks on the skin, in various parts of the body, and the use of the fluorescent screen. The next part is devoted to a general review of concretions, such as genito-urinary calculi, gall-stones, and so forth. Then follow discussion of bone and joint affections, deformities, tumours, and pathological changes in the soft parts, luxations and distortions, and fractures. All these, occupying 79 pages, are illustrated with outline drawings of radiographs. The rest of the volume consists of the atlas proper, of autotype reproductions of roentgenograms dealing with 438 subjects with descriptive text, a great many of which are illustrated with more than one or two films. This is a valuable book of reference and of pathological study for the radiographer, the pathologist, and the surgeon, for it is broad based on a great mass of accurate observations.

An unusual title for a monograph of over two hundred pages is *L'Hypochlorémie*,[2] by Marcel Rudolf, published recently by G. Doin of Paris. Diminution in the amount of sodium chloride in the blood plasma hypochloraemia is well known to occur in such diverse conditions as acute intestinal obstruction, diabetes mellitus, repeated vomiting, and some forms of nephritis. Often, in these cases, there is also a high retention of nitrogenous products in the blood. The opposite condition of salt retention is much better known to us, and is believed to have some influence on the production of renal oedema. Dr Rudolf has tried to unravel some of the problems involved in what may be conveniently termed the metabolism of sodium chloride in the body, but it is not his fault that he is able to give us little practical help. The problems are there, but at present are not capable of solution, and this monograph is therefore premature. The bibliography, almost entirely of French publications, is useful.

The *Trial of Alfred Arthur Rouse*,[3] a volume in Hodge's Notable British Trials Series, is edited by Helen Normanton, who outlines the main circumstances of the case ("the blazing car mystery") in a useful introductory chapter. Among other points she refers to the discrepancies in the reports by the three police officers who saw the body of the victim immediately after death, and to the fact that no medically trained observer was present before the body was removed. It may be recollected that Mr Justice Talbot, in his charge to the jury, expressed his astonishment that "the utmost care should not have been taken that the car and its contents remained as they were until they could have been removed to a proper place, having been properly examined." A full report of the trial is supplemented by appendices and illustrations.

CONSERVATION OF MAN-POWER IN WAR

Nothing comparable to the final volume of the *Medical History of the War*[1] has been produced by any other of the countries which took part in that great conflict. France and Germany have limited their analyses to cases treated in their base hospitals, while the American records are concerned only with one period of the struggle, and that confined to one front. This British account analyses and classifies more than eleven million casualties suffered by the British Expeditionary Forces at home and over-seas, but, owing to unavoidable omissions, even this enormous figure is not complete. The term "casualty" includes both battle and non-battle casualties, whether temporary or permanent. Non-battle casualties embrace all cases of sickness and of injury not due to enemy action. Vast as the published records appear, the work falls far short of the original intent. It had been hoped to add a complete classified analysis of some twenty-three million individual case records, but for reasons of financial economy it was finally decided to confine the analysis to the cards of British troops only, and, of these, to include only about a million cases taken in numbers proportionate to the strength of the various branches of the service.

The volume is not a medical treatise. The authors' aim is to present a study of the means of conserving man-power in war, and they show that an efficient medical service, properly supported, is a main factor in preventing wastage of man-power, and thus maintaining the fighting strength of troops in the field, a function of the medical services often overshadowed by stressing the humanitarian aspect of their work. The prevention of disease, a higher recovery rate, and a reduction of the period of detention in hospital, ensure a flow of trained reinforcements to the front. But it must be emphasized that the highest degree of professional skill may be rendered impotent if field medical units are unable to secure the rapid and orderly collection and evacuation of casualties from the line. Thus the provision of ample personnel, equipment, and transport not only lessens suffering, but gives a material return in the long run. It is a lasting monument to the skill and devotion of those responsible that 82 per cent. of the wounded, and 93 per cent. of the sick admitted to medical units in the great war, returned to some form of duty. The casualties caused by disease were twice as numerous as those of battle, whereas in the South African war sickness was responsible for about sixteen times as many admissions as the enemy. It is gratifying to learn, too, that in spite of the large proportion of wounds caused by shell fire, and the greater liability to septic contamination, the percentage of recovery was higher than in the South African campaign. Of over two million wounded who were admitted to casualty clearing stations, shell fire accounted for 58 per cent., rifle and machine-gun fire for 39 per cent., bombs for 2 per cent., while only 0.3 per cent. of wounds were due to the bayonet.

A striking feature of the statistical review is that the greatest temporary wastage of man-power was caused, not by the major epidemic diseases associated with armies in the field, but by the common and everyday ailments of ordinary life—diseases of the respiratory and digestive systems, rheumatism and its allied conditions, skin diseases, minor septic infections, and influenza. Although the dreaded and anticipated epidemics were kept at bay, other diseases of war broke out to swell the numbers of the sick, and to strain further the resources of medicine. The forgotten maladies, re-named trench foot and gas gangrene, reappeared, the former demanding the evacuation to the base of over 80 per cent. of those attacked. Trench fever, doubtless flourishing in earlier campaigns but then masked by typhus, called for long and sedulous research before its nature was disclosed. War nephritis was responsible for thousands of casualties, but its exact etiology baffled discovery. Dysentery and its allies—though never assuming widespread epidemic form—filled from first to last over 200,000 beds, and malaria twice that number. Paradoxical as it might appear, in the Eastern theatres of war victory was more to be feared as a causal factor of epidemics than defeat, for the occupation of enemy positions, always insanitary and often heavily contaminated, intensified infections already in evidence, and, at times, caused an outbreak of some disease which the force had previously escaped. The authors indicate how, in the unfortunate event of another war, the early misunderstandings and mistakes of the last can best be avoided; but, in justice to the medical services, it must be reiterated that the responsibility for a breakdown of medical organization cannot necessarily be laid to their charge. As is stated in the *Report on Medical and Sanitary Matters in German East Africa*, 1917: "The medical services are dependent on other departments, and if these fail them in any way, whether as regards supplies, transport facilities, disregard of advice, or slowness in taking action upon a recommendation, then the responsibility does not rest with the director of medical services."

Throughout the whole struggle in France and Flanders, the British Expeditionary Force incurred the astounding total of six million-odd battle and non-battle casualties. It staggers the imagination to picture what this vast host of sick and wounded demanded in the way of organization, accommodation, treatment, and transport. Some four million were evacuated from casualty clearing stations to the base, and over a million were transported across the Channel. Nearly three

[1] *History of the Great War Based on Official Documents. Medical Services: Casualties and Medical Statistics of the Great War.* By Major T. J. Mitchell, D.S.O., M.D., Ch.M., R.A.M.C., and Miss G. M. Smith, M.B.E., M.A. London: H.M. Stationery Office. 1931. (£1 1s. net)

millions of those admitted to hospital in France for wounds or disease returned to duty in the theatre of war, to which must be added the unstated number who returned to duty after evacuation to the United Kingdom. The general survey of the work of the Ministry of Pensions shows the appalling loss suffered by the nation in the form of post-war disablements. More striking than pages of descriptive writing is the bald statement that of the British forces, excluding Dominion and all other troops, 2,414,000 persons, or 40 per cent. of those who served, suffered death, or some form of war disability for which State compensation was required.

It would be impossible to praise too highly the form in which these masses of figures are presented. The narrative is written in an easy and attractive style, and technicalities are avoided as far as possible. To many the word "statistics" has a repellent sound, but here simplicity and human interest have not been butchered to make a mathematical holiday. This unique volume should be studied by every officer in the Army. It should be read, too, by all those concerned with the welfare of the nation, for should such another calamity overtake us, its teachings will reduce wastage of manpower, mitigate the sufferings of thousands, and lighten the residual financial burden of the State.

MEASLES CONTROL IN LONDON

The medical publications of the London County Council are distinct in cover and contents, usually repay perusal and the Report of the Medical Officer of Health and School Medical Officer on the Measles Epidemic, 1929–30[1], is no exception. Dr. Kay Menzies, in referring particularly to the last London outbreak of measles, has done well to put on record an account of how the perennial problem of measles is being tackled in the country's largest city.

The Health Department of the L.C.C., like other administrative authorities, realizes that the entire prevention of measles is a vain hope, even if such a consummation is altogether desirable, but efforts to control the disease, both in the manner of its incidence and in its clinical course are an objective which can, and should be, aimed at everywhere. The scheme at present used for dealing with the biennial outbreaks in London is based on certain primary considerations, and (as the report points out) is the result of many previous administrative adventures. In the first place, it is realized that among a large part of the population measles is still lightly regarded, despite the fact that in London during the past four years it has been responsible for eight times as many deaths as scarlet fever, and one and a half times the number of deaths from diphtheria. In the second place, many cases, partly because of this complacency, are either not brought to the notice of the Health Department, or, if so, are reported only when the children are seriously ill. Thirdly, in order to minimize the risk of a fatal result, the incidence of the disease among children under 5 years of age, and more especially under-nourished children living amid insanitary surroundings, should, as far as possible, be prevented. Lastly, it is recognized that to prevent the development of complications and to reduce the mortality, good facilities for home nursing, and medical treatment in hospital or otherwise, are essential. The scheme is administered by the County Council in co-operation with the various metropolitan borough councils and certain voluntary associations.

The leading part in the campaign is naturally taken by the school authorities, who utilize fully all their resources in personnel for the early detection of measles among school children, and for the instruction of parents. Thus head teachers, attendance officers, and school nurses are all concerned, not only with the detection of cases at school or at home, but also with the duty of promptly bringing all cases needing attention to the notice of the school medical officers and borough medical officers. In epidemic times the school nurses daily visit the infant departments of schools (and primarily those in congested districts) for the purpose of excluding from school and bringing to the notice of the medical officer of health concerned all suspected cases of measles, they also report to the district health visitor the names and addresses of all children absent from school. During the last epidemic no less than 53 per cent. of the suspected cases excluded by nurses proved to be cases of measles, and 41 per cent. of the absentees were also found to be suffering from the disease. But the school net alone is obviously not sufficient, and in two of the metropolitan boroughs (Paddington and Fulham) all cases of measles are notifiable, while in seven other boroughs the first case in each household must be reported. Partly through these means and partly through the vigilance of health visitors some 20,506 cases, in addition to the 34,494 discovered by the school authorities, were brought to light during the seven months ending June 28th, 1930.

A long and unrivalled experience has convinced the school medical authorities that neither class closure nor the exclusion of unprotected children is thoroughly successful in limiting the spread of measles in the schools. More importance is attached to the visitation and instruction of households where cases have been reported, or are suspected to exist, and to the instruction of households with young children situated within infected areas. Warning notices are distributed to these households, and among other matters attention is drawn to the fact that arrangements for the removal of a measles patient to hospital or for nursing assistance in the home may be made in special cases where the need for this is known to the borough medical officer of health. The London County Council as the result of the Local Government Act, 1929, is particularly fortunate in the possession of institutional facilities for the treatment of fever cases and in addition to the infirmaries and fever hospitals inherited from the late guardians and the Metropolitan Asylums Board, respectively, certain children's hospitals set aside a

[1] London County Council Measles Report of the Medical Officer of Health and School Medical Officer on the Measles Epidemic, 1929-30. London County Hall, Westminster Bridge, S.E.

limited number of beds for the study and treatment of measles cases.

During the recent epidemic 2,638 cases, 302 of which proved fatal, were admitted to the Council's general hospitals, and 6,452 to the Council's acute fever hospitals. The fatality rate for all cases in the latter hospitals was 6.5, but among the 1,847 cases admitted with complications the death rate was 20.4 per cent. Children who on leaving hospital are considered by the medical superintendent to need further care are, through the medical officers of health concerned, put in touch with the Invalid Children's Aid Association, and are enabled to continue their convalescence in suitable seaside or country homes. All the metropolitan boroughs have made arrangements under the Maternity and Child Welfare Act, 1918, or the Public Health (London) Act, 1891, for the home nursing of measles, and usually with the district nursing associations; in a few boroughs the direct employment of nurses for domiciliary treatment under the medical officers of health has been sanctioned. Dr. Menzies notes that little progress has so far been made in the application of serum treatment, either as a prophylactic or curative agent, but in the experience of Dr. F. Thomson and of other medical officers in charge of County Council cases convalescent serum used for prophylactic purposes has proved very useful; the supply, however, is too limited to meet the wants of hospital practice, apart from outside needs.

The report is instructive and interesting, and the account given of the administrative scheme for dealing with measles shows what can be achieved by a central authority co-ordinating all the resources at its disposal. The main result in this instance is that the number of deaths from measles among London school children has during the last twenty-five years progressively declined from 9,538 deaths during the period 1906–10 to 3,715 deaths during the period 1926–30.

CONTROL OF MALARIA IN PALESTINE

In practically every instance where a large number of non-immunes have been introduced into a highly malarious region the new arrivals have suffered most severely, and the disease has taken its toll in sickness and in human life. The determined attempt by communities of Jews to colonize in Palestine might almost have been doomed at its inception, and, indeed, because of the prevailing hyperendemic conditions might have proved a most disastrous failure, had it not been for the particularly able manner in which defensive measures were gradually introduced. In the near future it will be no empty claim that country-wide malarial control has been established. The volume by Kligler on the epidemiology and control of malaria in Palestine[1] is partly an account of the problems encountered and the measures undertaken in controlling the disease; it is also, in a way, a record of the excellent work done by the members of the Malaria Research Unit. The situation, as revealed, is a most curious one, and likely to appeal, not solely to the malariologist, but to the student of current events as well, for the social, economic, and racial tendencies have a definite bearing on the numerous factors influencing the incidence of malaria. Palestine is a country of mixed peoples, many religions, and all gradations of civilization, which vary in the country districts from the primitive, pastoral, nomadic Bedouin, through the grades of the native Arab agriculturists to the more progressive Jewish settlers. The Jewish colonists most frequently settled in the neighbourhood of that precious commodity, water, with the result that in a very short time malaria was rife, and, as in the village of Hulda, the settlements could only be maintained by annual replacement of part of the population. Beginning on a small and experimental scale, those conducting the anti-malarial campaign were soon able to extend the scope of their activities. One of the first signs of improvement was the changed attitude of the population, especially that section composed of the Jewish elements. Gone was the old indifference. And now a small outbreak of malaria in a Jewish settlement is the occasion for a storm. From the administrative side, also, the important principle is realized that it is neither good economics nor sound practice to settle people in malarious areas which have not first been subjected to adequate sanitary measures. As a result of the war experience and the data accumulated in the post-war period, it is now understood that malaria is eminently a local problem, and that a successful attack can be carried out only after a careful study of the local conditions combined with systematic experiments in control. Kligler has dealt with the subject in this manner; beginning first with topography and climate and a study of the social, economic, and health conditions of the inhabitants, he passes next to the consideration of the breeding places and bionomics of the anopheles. Then he deals with the incidence, etiology, and epidemiology of malaria, ending with a discussion of methods and results of control and experimental measures adopted in districts where anti-larval expedients had proved unsuccessful.

THE BUCKSTON BROWNE DINNER

The fourth Buckston Browne annual dinner of Fellows and Members of the Royal College of Surgeons of England was held on November 12th at the College in Lincoln's Inn Fields, with the President, Lord Moynihan, in the chair. The company numbered in all 105, the great majority of the guests being Fellows or Members of the College. Formal speeches were not made, but the President welcomed the guests in a few graceful words, mentioning in particular Sir Robert Hadfield, Sir Louis Barnett of Dunedin (President of the Royal College of Surgeons of Australasia), Sir Gerald Ryan, Professor Frederick Hobday (Principal of the Royal Veterinary College), and the Editors of the *Lancet* and the *British Medical Journal*. Lord Moynihan referred also to the forthcoming visit of Mr. C. H. Fagge to the Antipodes, when he will present a silver mace to the Royal College of Surgeons of Australasia. This work of art, designed and executed by Mr. Omar Ramsden, was on view after dinner. A dedicatory inscription records that it is "The gift of

the President and Council of the Royal College of Surgeons of England, as from brothers to brothers, MCMXXXII." In proposing the health of the donor of the banquet, Lord Moynihan described Mr. George Buckston Browne as the greatest benefactor of medicine in recent times Mr Buckston Browne, in a brief acknowledgement, spoke of his pride at being surrounded by pioneers in every branch of modern surgery, and his admiration for the enterprise and zeal for research shown by Fellows of that great College. He himself was no believer in finality in surgery, and he had great hopes for the future of the surgical biological research station at Downe. Sir Louis Barnett said that the visit to Australia and New Zealand of Professors Wright and Buckmaster, as examiners for the primary Fellowship, had been a great encouragement, and the mace would be valued by Australasian surgeons as a symbol of friendship and good will Each person present at the dinner received as a gift from Mr Buckston Browne an illustrated catalogue of portraits and busts in the College, with short biographical notices.

VITAMINS AND BONE GROWTH

"Cod-liver oil and the vitamins in relation to bone growth and rickets," by H. A. Harris, is an essay that was awarded the Alvarenga prize of the College of Physicians of Philadelphia in 1930.[1] It is a critical disquisition written in a bright and provocative manner The author scores amusing but somewhat cheap points against research workers on account of the frequent changes of doctrine that have occurred owing to the rapid development of vitamin knowledge He has sounder grounds for his criticism of the way in which every new discovery has been immediately subjected to commercial exploitation. In his introductory remarks Dr Harris says: "I propose to consider the history of cod liver oil in therapeutics, as it affords a singularly clear example of the manner in which the empirical common sense of the layman has triumphed over the alternating scepticism and hasty speculations of the scientist, and, in particular, of the biochemist in medicine." This inquiry leads the author to the conclusion that the most reliable weapon in the treatment of rickets is cod-liver oil "The recognition of the merits thereof is not due to any specific contribution to clinical medicine in these days, but, as is the case with so much in life, is part of the wonderful clinical heritage of the past" The fact that this essay has received the approbation of an important medical foundation makes it necessary to consider these conclusions carefully. They are simple and unqualified, and appear to us to be contradicted by the statements contained in the essay itself The author mentions that cod-liver oil was used as a household remedy by the inhabitants of the Atlantic sea-board in very early times, that it was introduced into English medicine in the latter half of the eighteenth century and that Schutte in 1824 described its curative action on rickets, stating that the oil would produce a cure in from five to nine weeks. This is in agreement with the conclusion that has been quoted, but the author goes on to point out that in 1912 one of the leading London paediatricians affirmed in relation to rickets: "There seems no specific virtue in cod-liver oil any other oil will do equally well." We may add that reference to the standard medical textbooks published in the early years of this century will show that this attitude was the usual one, for most writers at that period emphasized the disadvantages of cod-liver oil, and suggested that it was an overrated remedy. To us the salient facts appear to be that clinical workers, untroubled by any biochemists, had full opportunity for more than a century to study the action of cod-liver oil on rickets A few persons of exceptional acumen recognized clearly the remarkable specific action of cod-liver oil on rickets, and described its effects in detail. In spite of this clear lead the majority of clinical authorities failed to recognize the virtues of the oil, and severe rickets continued as a common disease Direct experimental proof that rickets could be prevented or cured by fat-soluble vitamins was provided by E. Mellanby in 1918, but this conclusion was vigorously opposed by a substantial body of clinical opinion, and it triumphed only because the combined experimental and clinical evidence was overwhelmingly in its favour It is a matter of historical fact that experimental work on vitamins has been followed by a far greater advance during the last ten years in the prevention and cure of rickets than that made during the previous century by clinical observation unsupported by experimental evidence. The only conclusion we can draw from this history is that the recognition of the merits of cod-liver oil in rickets was directly due to the provision in recent years of certain experimental evidence, and we do not understand why the author considers that it proves the opposite.

THE WINSFORD ANTE-NATAL SCHEME

Since 1930 an ante natal scheme depending on general practitioner service has been in action at Winsford in Cheshire, and has proved to be more appropriate to the district than an ante-natal clinic run in connexion with the child welfare centre During all the years the ante natal and maternity centre was in nominal existence, "only one single woman" attended for examination (We assume that this means only one woman—married or single) The urban district council therefore put forward a general practitioner scheme which was accepted, after some legal delays, by the Ministry. At the present time the council pays 10s 6d for the examination of every pregnant woman who is not insured under the National Health Insurance Acts no fee is paid for the examination of an insured woman but the medical practitioners under the scheme supply reports to the medical officer of health on patients of either class. In his annual report as the medical officer of health for Winsford, Dr L J Picton suggests that a fee of 7s. 6d. for each class of patient would be more equitable. Under the National Insurance Acts but patients are entitled to free ante natal supervision by the doctor is under no obligation to supply a report on the case to the municipal authorities. In Winsford the majority of women are not insured but in an area with a large insured population a fee for all reports would be essential if local practitioners were expected to undertake the extra office work involved. Between the spring of 1930 and the summer of 1931 104 reports were received under the Winsford scheme by the medical officer of health The reports are made out

[1] Am. Journ. Med. Sci., April, 1931.

on a form which covers the previous obstetric history of the patient; the date of the first ante-natal examination and the findings, including pelvic measurements; the constituents of the urine; details of the general health, with special reference to the state of the teeth, digestion, heart, and lungs, and to the presence of oedema, varicose veins, piles, or anaemia; the findings at a second examination late in pregnancy; and the history of the labour. Each item is dismissed in a word or two, but the result is a concise yet comprehensive picture of the case. The county council has accepted the principle of an ante-natal scheme run by general practitioners for application elsewhere in the county, and it will be interesting to observe whether similar schemes are adopted for general use in Cheshire.

ASTHMA RESEARCH

In a report of progress from June 1st, 1930, to October 31st, 1931, the Asthma Research Council outlines the work that is being undertaken at its various research centres. New methods of treatment have been introduced, and old ones modified, so that the average asthma patient can now be treated with more hope of success than was formerly possible. At the Guy's Hospital Clinic over three hundred patients have been investigated. While the main concern has centred round problems of the "urinary proteose" and the bacteriology of the sputum, factors such as diet, heredity, physical habit, lung lesions, presence of sensitization to food, dust, pollen, or animal emanations have also been studied. In the latter connexion the clinic expresses its desire to obtain examples of specific sensitization in which contact with particular substances induces asthmatic attacks. Patients with hay fever are also invited to attend—during the winter, if possible—in order that steps may be taken before the commencement of the "season." It is pointed out, in passing, that the aim of the clinic is to carry out an accurate study of individuals rather than to obtain statistical data from a large number of cases. Research has already shown that, during the asthmatic paroxysm, besides the occurrence of profound changes in the blood an albuminous substance is excreted in relatively large amounts in the urine. This probably contains an albuminous complex to which the patient is sensitive, and a protective substance elaborated against it by the organism. Hay fever patients and asthmatics excrete proteose during an attack, but whereas in hay fever proteose obtained from one patient can be used in diagnosis or treatment of another, in asthma a mutual proteose reaction is unusual. An exception is found, however, in specific sensitization cases where, as in horse asthma, the proteose is similar if the sensitization is the same. It is hoped that further studies in this direction may unravel the mechanism of the asthmatic paroxysm, throw light upon the more complex forms of the disease, and have a practical application in eczema and certain forms of rheumatism, in which a similar condition of proteosuria exists. A large number of patients have already been treated with desensitizing injections of proteose, and very satisfactory results are reported in some instances. Bacteriological investigation of the sputum has been concerned with the histamine-forming organisms found in both bronchial secretions and culture media taken from asthmatics, and though it is doubtful whether these bacteria can induce asthma by local formation of histamine, the good results obtained with vaccines made from them augur a promising line of investigation. Other matter reported from the Guy's clinic includes glucose and hygienic treatment in children, respiratory exercises, and the testing of unorthodox remedies. The use of sanocrysin in ten patients proved unsuccessful. The Hospital for Sick Children, Great Ormond Street, provides interesting information on hereditary and other aspects. In two out of every three cases some relative of the asthmatic child suffered from the disease. The affected relative was found twice as frequently on the mother's side as on the father's. On the other hand, three times as many boys as girls were affected before adolescence, while after this males and females were equally susceptible. Normal changes at puberty would therefore appear to be beneficial to the asthmatic boy and detrimental to the asthmatic girl. As a result of the inspection of many hundreds of homes it was concluded that the most common causative factors were feather or horsehair beds or pillows, animal pets, and dust. Investigation of food hypersensitivity revealed that the great majority of patients had deficiency or absence of acid gastric juice, with consequent inability to digest protein food. Work in the Department of Physiology at King's College deals with blood chemistry in relation to locality asthma, and the influence of certain articles of diet which, while not involving hypersensitivity in the ordinary sense, may upset the calcium, potassium, and carbon dioxide balance in the blood, and so prove harmful. Interesting research has also been done on the desensitization of the bronchial tubes. This opens up the possibility of desensitizing asthmatics at a single treatment, without the need for the innumerable injections which have hitherto been necessary.

DR. GUILLOTIN

At a meeting of the Osler Club on November 13th, Dr. J. D. Rolleston gave a short sketch of the life of Dr. Guillotin, whose name is linked with the instrument of capital punishment introduced at the time of the French Revolution. Joseph Ignace Guillotin was born at Saintes (Charente Inférieure) in 1738, and after serving as professor of literature at the Irish College at Bordeaux, studied medicine at Rheims, where he qualified in 1768, and two years later obtained a doctor's degree in Paris. He subsequently acquired some distinction in the capital, as he served on a committee appointed by the Government to inquire into Mesmer's exhibitions, and was made one of the ten deputies of Paris in the Assemblée Constituante. On October 10th, 1789, he made a proposal to this body that there should be a uniform method of execution, by decapitation, in place of the barbarous methods hitherto employed, such as burning, mutilation, drowning, and hanging. The Assembly, however, was moved to laughter when he claimed that a machine which he had invented caused an immediate and painless separation of the head from the trunk, and it was not until two years later that a law was passed that everyone condemned to death should be decapitated. At the request of the Assembly Dr. Antoine Louis, the perpetual Secretary of the Académie de Chirurgie, who died peacefully in 1792 (and not, as has been erroneously stated, by the guillotine), drew up a report in which he called attention to the fact that decapitation

by a machine was already in use in England, and stated that it would be easy to construct a similar machine in France. Louis might have added that a similar machine had been employed in Germany before the middle of the sixteenth century, and also in Italy at the beginning of the eighteenth century. The engine of the law appears finally to have been made by the collaboration of Louis with Schmidt, a German pianoforte maker, and Sanson, the notorious executioner, but without Guillotin's help. The instrument was indeed at first called "la petite Louison," or "la Louisette," before the name "guillotine" was finally substituted. Dr. Rolleston suggested that the legend that Guillotin was one of the first to perish by the machine to which his name was given rested on the fact that Fouquier Tinville had him thrown into prison on discovery of a letter from a Count Méré about to be executed, commending his wife and children to the doctor's care. Guillotin, however, was subsequently released on the fall of Robespierre, and lived until 1814, when his death was due to a carbuncle of the left shoulder. It is noteworthy that Guillotin was one of the earliest French supporters of Jenner's discovery, and in 1805 was made president of a comité de vaccin in Paris.

CANCER AND TUBERCULOSIS

Dr. Thomas Cherry of Melbourne published his first papers on the relationship between tuberculosis and cancer in 1922, and as a result of statistical studies he came to the conclusion in 1925 that the correlation between the two diseases was so intimate that experimental research was necessary to test his new definition of malignant disease. This definition ran as follows: "Cancer is in most cases the expression of the resistance of the cells to a second or subsequent invasion by the *Bacillus tuberculosis*." He then proceeded to carry his work a step further by experiments on mice, and two papers—the fifth[1] and sixth[2] in this series—have recently been published. The former of these deals with the results of inoculating 879 mice with tubercle bacilli, the dose being on the average of the order of 50,000 bacilli. A certain number of the mice have died of what is called pseudo-tuberculosis, etc., and over two hundred are still alive, so that available for the report are 349 mice, which are compared with a control group of 305 mice, all over 6 months old. In the inoculated group 80 tumours have occurred, as compared with 9 in the control group, giving a percentage incidence of 23 and 3 respectively. The classification of these tumours indicates that they exhibit an absence of uniformity and site distribution as erratic as in human cancers. The mamma is one of the principal sites, but does not show the overwhelming preponderance seen in spontaneous tumours of the mouse. The commonest site is in the gastro-splenic region and the mesentery, where a persistent lymphocytic infiltration associated with enlarged glands is often found. A group consisting of tumours of the skin and pancreas and some of the sarcomata furnishes strong evidence that they have been caused by the inoculations. For example, four cases of skin epithelioma occurred in the series, and since epithelioma is rarely seen in mice, and all this group appeared close to the site of inoculation, there seems ground for assuming some causal connexion. It is not suggested that the tubercle bacillus is directly connected with tumour formation, but rather that the bacillus must be added to the list of carcinogenic irritants. It has been observed that in the tissues adjoining the tumours there are many collections of lymphocytes, and these cells are prominent features of nearly all the lesions of this experimental group of mice. To this point Dr. Cherry returns in more detail in the sixth paper of this series. Here he compares the appearances found in the gastro-splenic region in 50 mice inoculated with tubercle bacilli with those in 50 control mice affected with a spontaneous outbreak of pseudo-tuberculosis. This is a disease occurring in mice and other rodents caused by an organism of the plague group. In the pseudo-tuberculosis group the infiltrating cells about the pancreas are almost exclusively polymorphonuclear leucocytes, while in the inoculated group the dominant cell is the lymphocyte. Dr. Cherry suggests that since the polymorph is the characteristic cell of septic conditions in the mammalia there is an antagonism between such conditions and cancer. Chronic wounds, he observes, seldom become malignant, and there is a well-recognized antagonism between cancer and florid phthisis. Conversely, conditions where a lymphocytic infiltration is characteristic are more prone to undergo malignant change. He argues that "the lymphocytes take an active share in the production of malignant disease, and are an essential link between the mouse and the malignant cell."

WELLCOME RESEARCH INSTITUTION

Lord Moynihan, President of the Royal College of Surgeons of England, will lay the corner-stone of the Wellcome Research Institution on Wednesday, November 25th, at 2.30 o'clock. This is the new building now in course of erection in Euston Road and Gordon Street, W.C. When completed the institution will embrace the following affiliated laboratories and museums: bureau of scientific research, physiological research laboratories, chemical research laboratories, historical medical museum, and museum of medical science. The architect's design for the building was exhibited at the Royal Academy last summer.

The biennial Huxley Lecture on recent advances in science in their relation to practical medicine will be given at Charing Cross Hospital Medical School on Thursday, November 26th, at 4.30 p.m., by Sir Almroth Wright. His subject is "Immunity: the old doctrine and the new." Admission to the lecture is free by ticket, to be obtained on application to the dean of the School, Chandos Street, W.C.2.

The seventh Norman Lockyer Lecture will be delivered before the British Science Guild by Dr. H. H. Dale, secretary of the Royal Society, on Tuesday next, November 24th, at 4.30 p.m., in the Goldsmiths' Hall. The subject of the lecture is "Biology and civilization."

Sir E. Farquhar Buzzard and Mr. W. Sampson Handley have been appointed members of the Advisory Committee on the Administration of the Cruelty to Animals Act, 1876, in succession to Sir Archibald Garrod and Sir Charters Symonds, resigned.

ROYAL SOCIETY OF MEDICINE

ANNUAL DINNER

The annual dinner of the Royal Society of Medicine took place at the May Fair Hotel, London, on November 12th, when Dr. T. WATTS EDEN presided over a company of about 150 Fellows and guests. The principal guests were: Sir William Bragg, Sir George Buchanan, Sir Farquhar Buzzard, Lord Dawson of Penn (President, Royal College of Physicians), Dr. F. E. Fremantle, M.P., Sir Henry Gauvain, Sir Ernest Graham-Little, M.P., Sir F. Gowland Hopkins (President, Royal Society), the Right Hon Sir Donald Maclean, M.P. (President, Board of Education), Sir Ewen Maclean, Sir Milsom Rees, Mr. Herbert Tilley (President, Medical Society of London), and Dr. W G. Willoughby (President, British Medical Association).

At the reception the President wore a new gown, maroon in colour, copied from the robe of a doctor of medicine of Padua of the eighteenth century, as illustrated in a volume in the library of the Royal College of Physicians. The gown is a gift to the Society by Lord and Lady Dawson, who have spent a great deal of time upon its selection and production. The fabric is of British manufacture, and the garment was made in Scotland.

Sir DONALD MACLEAN, in proposing the toast of "The Society," made a passing reference to his recent electoral struggle, mentioning the fact that one of the reasons for his success was the fact that his brother (Sir Ewen) spoke very often on his behalf, and nobody had any idea to which party he belonged! His own profession, that of the law, Sir Donald went on, owed a great deal to the Romans, while the medical profession owed much to the Greeks. Unfortunately, the Greeks had no method of centralizing medical education and science and of standardizing teaching. What might medical science have been to-day if in those far-off times there had been a Sir John Macalister to fuse into one great royal society the medical library at Alexandria, the school of Cnidus, the school of Cos, the Sicilian school, not to speak of Herophilus and Celsus! He proceeded to say a few words about the Board of Education and such efforts as it had made to promote the well-being of children in the schools. He found on taking office that he was responsible for 1,300 school medical officers, 3,000 school nurses, 1,000 specialists—"whatever that may mean"—and 750 dentists. Sir George Newman, for whose work in connexion with public health the nation owed a great debt of gratitude—in his recent report stated that since this national service was established in 1907 hundreds of thousands of defective or ailing children had been effectually treated and their physical disabilities remedied. In a word, there had been provided repair on a vast scale. "I am by no means unacquainted," Sir Donald Maclean went on, "with the difficulties which are obvious, and indeed unavoidable, as between the medical services attached to the various State departments and the great outside practising profession. Let me express the hope that I shall never live to see the day when the voluntary practice of medicine is in any degree lessened, but I am quite sure there is not only room, but ample opportunity, for a much larger measure of co-operation and co-ordination between the medical services of the departments of the State and your own great organization. I know that this is very difficult ground, but I will only say—and I say it officially—that if there is anything which the Board of Education can do by way of co-operation and co ordination and friendly working together, it shall gladly be done. I am sure that is the best line of progress instead of endeavouring to drive unwilling units under the State umbrella." With regard to the Royal Society of Medicine, he said that its record showed what an immense amount of work could be done by skilled and friendly co-operation. It was a great federation of medical and surgical activities. Within it the physician could tell the surgeon what he thought of him, and the surgeon could equally tell the physician. It was a pity that there was not a department for eliciting the frank opinion of the patients. But the great work which had been accomplished was evident to all those who took the least care to see and read what had been done. "You have no difficulties about dumping at all; I welcome you all as free traders. You exclude no knowledge which is of the slightest use to the human race, come from where it will. But I am very conscious of the fact that there is nothing quite so good in the medical and surgical world as home products, and I am very proud of the fact that the great medical profession, as practised in Great Britain, stands at the highest point which the profession has ever reached in any country, not only scientifically, but ethically also. I know that some people talk about doctors' etiquette in terms of impatience, and occasionally it is possible that such impatience may be justified. But that etiquette is only a symptom of a profoundly vital fact in the realm of progress of general medicine, and in what you do among yourselves in your profession you set a splendid example to the whole world."

Dr. WATTS EDEN, in responding, said that the Society was really a great organization by means of which medical men and women were carrying on their own education, and the wise founders of the Society built upon the very broad foundation of "physick and surgery and the sciences connected with them." Its interests were therefore catholic and not sectarian, and although the Society carried on its work by means of a large number of Sections, each concerned with its own corner of the medical field, its real object was medicine as a whole. Medicine was now a highly specialized subject, and in consequence was in some danger of becoming split up into disconnected units, each having but a narrow and limited outlook—a keyhole view, as it were, of the whole field. This outlook was inimical to broad views of disease, of diagnosis, or of treatment, and if a specialist, no matter how distinguished he might be, strayed from his own

path, he was in danger of becoming a nuisance. The Society supplied the corrective to that tendency, for it could offer to physicians an insight into surgery, to surgeons an insight into medicine, and to specialists an insight into both, to the very great benefit of them all. It formed a cohesive power which would help to promote the unity of medicine, to prevent exaggeration by men of one brilliant idea, and thus to keep practice upon an even keel; and if medicine was to give the best service to the nation an influence such as this was clearly needed.

In closing, Dr. Eden referred to some indications of vitality which the Society had recently shown, including the creation of the Sections of Physical Medicine and of Radiology. He thought that this was a happy indication of the elasticity of its constitution, and of its readiness and ability to meet fresh requirements as they arose.

Mr. W. Girling Ball, in proposing the health of the guests, referred to each of them in complimentary terms. Sir Donald Maclean, he said, represented the National Government, and he and his colleagues had taken up a task which was as difficult as any body of men had been set to carry out during the history of the nation. With regard to Sir William Bragg, it was particularly delightful to have him as a guest in the year in which the centenary celebrations in honour of Faraday had been held. Sir William was the apostolic successor of Faraday in the Fullerian Professorship of Chemistry, and he had little doubt that when the centenary of that great man came round again the name of Bragg would be found coupled with his, so well had he carried on the tradition. Among the medical guests, the Society offered its congratulations to the President of the Royal College of Physicians, Lord Dawson of Penn. It was difficult to think of him as a guest, for he was the immediate Past-President, in which capacity he had served the Society well. During the time of his presidency he passed through the harassing months of the King's illness, and although they all knew how trying a time he had had, he would come from the royal sick chamber into their midst apparently completely unruffled. Other guests to whom he extended a welcome were Mr. Tilley, the President of the Medical Society of London, which claimed to be the oldest of all the medical societies, and Dr. Willoughby of Eastbourne, the President of the British Medical Association, who was the first medical officer of health to become President of that body. The medical press were always welcome, for it was through their aid that the wisdom—or the folly—which was spoken in the Society was transmitted to the unfortunate people who did not happen to be its members. The medical journals performed a great service by co-operating in every way in the Society's work, and gave their services ungrudgingly.

Sir William Bragg, in his reply, referred to some of the contributions of the physical sciences to the health and well-being of the nation. He said that he had looked through lists of works in various libraries, and it was remarkable how much scientific research in this country was directly connected with health. He was thinking of subjects rather of a wide character as related to the general well-being, such, for example, as the work done on the refrigeration of food, on the measurement of noise, on the distribution of light, and on the detection and removal of pollution from the air and from water. There was an interesting distinction between the ways of applying the knowledge so gained. It might, to take an example from the work on sound, be used for the design of instruments which measured the amount of noise in a room or street, with a view to aiding the guardians of the law in prosecutions for offences. Such instruments would have to be extremely complicated if they were to record not only the actual amount of energy of the noise, but also the many other concurrent effects which helped to determine whether the noise was a nuisance. They might be valuable as deterrents, but the prevention of offences was better than prosecution for infringement. It was possible to measure noise, but not to trust the instrument for so doing in the hands of a policeman. The results of scientific research were best applied to the design of streets, buildings, rooms, machinery, and so forth in such ways as to reduce unnecessary noise or glare or deficiency of light or atmospheric pollution. It was now known, generally speaking, that it was possible before a building was put up to determine exactly what would be the consequences in the way of sound and lighting, as well as other characteristics, and it might be that these utilitarian considerations would render the building less dignified or beautiful. But when those who had to do with design and construction in building knew beforehand what could be done in this respect a very great power was placed in their hands. It was possible, for example, so to treat a room that all sounds would be perfectly well heard in every part of it, also to distribute the illumination so that the source of light would scarcely be noticed and yet be wholly satisfactory. All this was due to quite modern effort; and, as showing how modern the science of illumination was, he mentioned that in an encyclopaedia of not any great age, on turning to "illumination" he read "see 'fireworks'"; A great deal of comfort, in respect to silence and other matters depended upon architectural design. The ancient Romans understood this, as witness the dwellings at Pompeii, when they placed the backs of their houses to the noisy streets. These were but isolated examples of the knowledge that was now becoming general, and the more such knowledge was available to those responsible for the health and comfort of the community the less frequent would be the occasions for offence.

HEALTH OF THE SCHOOL CHILD

SIR GEORGE NEWMAN'S REPORT

[Second Notice*]

Nursery Schools

Nursery schools offer one method of providing supervision for the pre-school child. Of approximately two million children between the ages of 2 and 5 only about 3,000 are in nursery schools, about 160,000 are in the ordinary elementary schools, and the rest at home. There are now 44 recognized nursery schools with accommodation for 3,335 places. The experience of the last twelve years shows that the nursery school child is less susceptible than others to the ordinary ailments of childhood, particularly those of a catarrhal and rickety nature. The advantages of fresh air, rest, and suitable diet prove of inestimable value in raising the resistance to tuberculosis. In Manchester the "nursery class" in the ordinary school has been found a less costly form of provision. But premises are not always suitable, playgrounds have to be shared, and the infants do not get undisturbed sleep. Bradford has experimented in joint nursery schools and infants' departments. The object has been to avoid the break in school life which comes when the child is transferred from the nursery school to the elementary school. It is claimed that this plan brings the best of the methods and atmosphere of the nursery school into the infants' department.

Open-air Schools

There is now accommodation for 10,162 in day schools, and 3,278 in residential, an increase of 2,200 places on last year. The influence of these schools is wider than this. At the present time 89 per cent. of the school building plans submitted to the Board for approval contain proposals for throwing open to the outside many of the class rooms—a very valuable method of extending the open-air principle. One of the chief problems is heating. During cold weather the children attending unheated open-air schools are not able to work with more than about half the average efficiency of children attending warmer schools, and even then they need special aids to the

* The first notice of the annual report of the Chief Medical Officer of the Board of Education for the Year 1929 appeared in the *Journal* of November 14th (p. 913).

maintenance of bodily warmth, such as extra food and extra clothing. It may be urged, however, that it would be better to allow a small loss of manual efficiency and a small reduction in attendance rates if such losses were balanced by an improvement in the health of the children.

Artificial Light Treatment

There is still a suspense of judgement on the value of ultra-violet light treatment. Many children undergoing treatment were also receiving other treatments at the same time by tonic or operation, also there is little doubt that the greatest improvement occurs in cases which from the nature of the defect have a natural tendency to improve apart from any special form of treatment. Nevertheless, there is a general agreement that for the debilitated child, and especially the child weakened by acute illness, artificial light has a definite if not a precisely measurable value. The signs of improvement are to a large extent subjective—increased activity, improved appetite, more refreshing sleep. Objective signs, such as increase of weight and improvement in the percentage of blood haemoglobin, are less constant. As a means of preventing the common cold actinotherapy has been generally disappointing ; indeed, a recent investigation in America indicates that the irradiated group has a slightly higher incidence of nasal catarrh than the control group! Similar difficulties arise in the evaluation of the light in rheumatism ; some observers found much remission of the symptoms, so that when the radiation was stopped there was a request for second courses ; Leicester, on the other hand, reports "no effect was noticed in the rheumatic cases." No definite evidence is found that the light has any advantage over local treatment for impetigo and other septic conditions of the skin. For external eye diseases such as blepharitis and phlyctenular conjunctivitis there were diversities in the reports ; some considered it a useful adjuvant to other forms of treatment, but most areas indicated a very limited amount of success. The present conclusion is that artificial light has a tonic effect on debilitated children, but it must in no sense be regarded as a substitute for proper feeding, natural sunlight, and improved environment. As Dr. Atkinson of Manchester notes: "Children coming from good homes or fairly good homes do well, but those from really slum areas do not benefit to so great a degree from the treatment." The evidence tends to show that the light has little or no effect in the prevention of colds or other infectious diseases.

School Feeding

Observations have been continued upon the state of the children in mining areas. It appears that remedial measures are effective, save that in colliery districts and in some large industrial areas there are more or less isolated pockets of a socially inferior population, and it is in these that the greatest incidence of malnutrition is to be found. The value of milk as a supplementary ration was investigated in Lanark ; 10,000 children received three-quarters of a pint daily, another 10,000 none. The addition of the milk to the diet of the children had a striking effect in improving physique and increasing mental alertness. It is suggested that milk may enable other constituents of the ordinary diet to be fully utilized as growth factors.

The Problem of the Cripple Child

There is a steady development of the provision of clinics, hospital accommodation, and education for cripple children. Results are now under investigation. To the question whether these cripples are being mended and returned to the ranks of the normal school children or being made fit for employment, there is given the answer, Yes. In Leeds, of every 100 children treated 75 have been returned to school. In Bath also 75 per cent. were able to lead a normal life. In Manchester, of 140, as many as 90 went into ordinary employment, 20 were unemployable, and 25 went to the ordinary school. In Shropshire, of 1,671, 67 per cent. returned to school, though many of them were serious cases. Apart from treatment they would have been likely to become, and remain, physical derelicts.

Physical Training

A notable development has taken place owing to the generous offer of £30,000 made by the Carnegie United Kingdom Trust, for the purpose of providing a Physical Training College for men teachers. The Leeds local education authority have this year decided to erect a building to be known as Carnegie Hall, in connexion with the City of Leeds Training College and in its grounds at Beckett Park. The intention is to provide an institution of a national character to fill the gap hitherto existing in the facilities available for men teachers of physical training. There will be one-year courses for teachers who have completed a two-year course in an ordinary training college or university training department. It is not intended that the institution should give training in this subject to those who are not qualified as teachers generally, for it is not desirable that the subject should be in the hands of those whose qualifications are limited to physical training, nor is it in the interests of the teacher that he should be limited to a subject which he can rarely hope to teach effectively after middle age. In addition to these courses there should be ample opportunity of organizing short refresher courses of great value. Plans of a building to accommodate about sixty students and staff, and of a gymnasium, have already been approved.

Among the appendices to the report will be found a list of inquiries and researches undertaken by school medical officers and their colleagues. The list shows between eighty and ninety separate reports: eight researches into enlarged tonsils, adenoid, and throat diseases; eight into rheumatism and its effects in childhood and adolescence ; four into epidemics ; more than a dozen into nutrition ; and some forty to fifty into current problems arising out of routine work. This is evidence of keen interest and vitality in the school medical service.

India

Medical Services of the G.I.P. Railway

The annual report of the medical department of the Great Indian Peninsula Railway for 1930–31 affords an interesting example of the way in which the general public health is promoted in the districts served by this organization. Thus, the railway lands are regularly inspected by the health staff under the direct control of skilled investigators of malarial conditions ; destruction of the mosquito larvae is systematically organized, their breeding being prevented by levelling and drainage operations where indicated by careful preliminary surveys. Reports on the results of the various anti-malarial measures are received and collected. In the Bombay district, for instance, 8,801 actual and potential breeding places were treated with nearly 10,000 lb. of crude oil during the year under review. In the Igatpuri district the staff quarters and their surroundings were regularly inspected in order to detect mosquito breeding places; drains were cleared of vegetation, wedges soaked in oil were kept ready for their automatic oiling, and specimens of larvae were examined for identification. In the Bhusaval district the conclusion was reached that the River Tapti constitutes a very serious source of malaria, and is an obstacle to measures undertaken for its control. Adult mosquitos collected during October and November

when the incidence of malaria was high, revealed that the percentage of the anopheline species was 2.6, as compared with the culicine. It is obvious from the report that the railway is compiling a most valuable series of records indicating the prevalence and distribution of malaria centres and the relative efficiency of the different ways of dealing with dangerous conditions. The influenza rate among the staff increased slightly as compared with the previous year, but decreased among the members of the families of employees. The incidence of venereal disease was slightly higher; evidence is being obtained that infection is too often concealed, and that treatment is not being obtained. There was also a slight rise in the incidence of pulmonary tuberculosis and of enteric fever, but plague and small-pox have been kept down by prophylactic inoculation. Measures of economy are being undertaken, the effect of which will be recorded in the next annual report. The main line of policy followed has been the maintenance of the best medical facilities suitable for the railway employees and their families, economies being effected by closing dispensaries wherever this proves practicable.

Medical Aid in the Central Provinces and Berar

Regret is expressed by Colonel F. E. Wilson, I.M.S., Inspector General of Civil Hospitals in the Central Provinces and Berar, in his annual report for 1930, that the establishment of a large number of dispensaries has had to be postponed owing to the inability of the Government to contribute its share towards the scheme, in consequence of the prevailing financial stringency. It appears that the local bodies concerned were prepared to pay their quota, and that the required subscriptions had been collected locally. Temporary camp dispensaries in areas afflicted by famine proved very effective in dealing with outbreaks of disease. The scheme for subsidizing medical practitioners settling in villages was continued during the year, but the working of some of the dispensaries conducted by them has proved very disappointing. An investigation of the scheme as a whole is therefore being undertaken with a view to determining whether the degree of success justifies the expenditure incurred. The treatment of leprosy in certain dispensaries has won little popularity, and the suggestion is made that it would be preferable to deal with these patients in their own homes by a travelling dispensary. The social stigma of this disease is very great, and there is a strong natural desire to conceal it. It is felt, however, that unless a small area is chosen, and two assistant medical officers are appointed to it—one to give treatment at the hospital and the other to carry on intensive propaganda throughout the year—the experiment is not likely to be attended with the success it deserves. It happened, unfortunately, that no grant in aid of the free treatment of pauper lepers could be given during the year. The training classes for probationer nurses at the Mayo Hospital, Nagpur, continued to do well, and a new class has been started at the Victoria Hospital, Jubbulpore. Health propaganda lectures are being delivered by all assistant medical officers in charge of outlying dispensaries; the system of distributing simple remedies through village schoolmasters has been started at two centres, with very encouraging results.

Prevalence of Infantile Biliary Cirrhosis

An attempt has been made in the State of Mysore to determine the relative extent of the incidence of infantile cirrhosis of the liver, and to collect data relating to the probable causes of disease, with the ultimate object of discovering means for its successful treatment. A preliminary report has now been issued by the Government of this State covering the work undertaken during the first six months of 1930. Instructions to the various medical officers and their subordinates to report cases of infantile cirrhosis coming within their cognizance were not very fruitful, but the survey of conditions in the districts, though cursory, has afforded a useful supplement to the systematic work in progress at Bangalore. Most of the cases recorded were among Brahmin infants, males seeming to be more prone to this condition than females, and the onset being most commonly between the ninth and fifteenth months of life. Poverty was indicated as an important factor, but the question of diet seemed also to have special significance. The disease was particularly prevalent in certain areas, and these are now being investigated more carefully with a view to finding out whether vitamin deficiency is one of the etiological factors. Two dietetic customs, the 'malnad' and the 'maidan,' have to be considered in this respect. The first of these implies the giving of cow's milk as a routine from birth; it is highly adulterated, germs with bacteria, and nothing is done to bring its composition as far as possible to that of human milk by dilution and the addition of cream and milk sugar. Rice is given as early as the fourth month of life, fruit juices are omitted from the infant's dietary, and fat in the form of ghee is probably administered beyond the child's requirements. The 'maidan' custom is to delay the administration of cow's milk somewhat, and rice does not enter the dietary until after the ninth month. A comparative study of the effects of these customs is in progress. The maternal health was usually found to be poor, malaria and helminthic infections being common. The quality of the mother's milk is thus impoverished, with consequent deterioration of the health of the child. Investigation of the stools is in progress with a view to discovering whether some specific protozoan or infection is concerned in causing the hypochromia characteristic of the early stages of infantile biliary cirrhosis.

Scotland

Child Adoption in Scotland

The annual meeting of the Scottish Branch of the National Children Adoption Association was held in Edinburgh on November 19th, under the presidency of Councillor Mrs. Monson Millar. The association is under the control of the Child Welfare Department of Edinburgh Corporation, and was founded in 1923, to obviate the unsatisfactory conditions then prevailing whereby children with a money bounty were adopted without medical examination. The chairman said that the society existed for the protection of the child, and took care that when adoption was necessary it was carried out, not for money payment, but for the sake of the child. In the last few years two hundred adoptions had been arranged, and the officials of the society kept in touch with these cases. For the reassurance of persons who were thinking of adopting children Dr John Guy, medical officer of health for Edinburgh, said that the health of any child adopted through the association was carefully examined beforehand.

Alcohol in Treatment

In a lecture [illegible] on November 5th, [illegible] Ward Temperance Association, Edinburgh, Dr. Macnicol said that physiological experiments [illegible] alcohol acted upon the nervous system [illegible] not as a stimulant. Alcohol had a [illegible] tion of increasing the vital activity [illegible] but it was now regarded as a depressant so that in hospitals and infirmaries much less alcohol was used than

formerly. The records of the Edinburgh Royal Infirmary, for example, showed that in 1861 the expenditure upon alcohol was £2 0s. 6½d. per patient, while in 1917 the rate per patient was 6d. Similarly in Liverpool and London hospitals the use of alcohol had greatly diminished, while the consumption of milk had proportionately increased. The real place of alcohol, the lecturer contended, was in certain cases of weakness when ordinary food could not well be taken, and food could to some extent be replaced by small doses of alcohol.

Medicinal Baths in Edinburgh

At a meeting of the Baths and Wash-houses Subcommittee of Edinburgh Town Council on November 13th, a report was submitted by Dr. John Guy, medical officer of health for Edinburgh, on medicinal baths, which it is proposed to install at the Warrender Baths in the city. It was stated that similar baths had already proved successful at Dundee, and that there would be an installation of sweating baths, pine baths, tonic baths, oxygen baths, and carbon dioxide baths, which would be advantageous for the treatment of obesity and rheumatism. It was resolved to recommend the Town Council to make a grant for the necessary structural alterations in the establishment.

Largs Infectious Diseases Hospital

At a meeting of the Largs Town Council on November 6th it was agreed to protest against the decision of the Ayrshire County Council to close the Clark Hospital for Infectious Disease at Largs. The proposal of the county council was to transport the patients with infectious disease from Largs to the neighbouring Springvale Hospital at Saltcoats. It was stated at the meeting that the Clark Hospital had been quite satisfactory, and that there was doubt whether the arrangements proposed by the county council on the grounds of economy would save any expenditure in view of the growth of the community. For the retention of the local hospital it was urged that in the event of a child becoming seriously ill, the parents could be summoned immediately.

England and Wales

Medical Women's Federation

The autumn council meeting of the Medical Women's Federation was held on November 6th at the Medical Institute, Fanning areas. A resolution was passed that medical ective, save that in colliefy available, for those wonge industrial areas there are more or amination pockets of a socially inferior population, and it is council that the greatest incidence of malnutrition is to be foon. The value of milk as a supplementary ration was investigated in Lanark; 10,000 children received three-quarters of a pint daily, another 10,000 none. The addition of the milk to the diet of the children had a striking effect in improving physique and increasing mental alertness. It is suggested that milk may enable other constituents of the ordinary diet to be fully utilized as growth factors.

The Problem of the Cripple Child

There is a steady development of the provision of clinics, hospital accommodation, and education for cripple children. Results are now under investigation. To the question whether these cripples are being mended and returned to the ranks of the normal school children or being made fit for employment, there is given the answer, Yes. In Leeds, of every 100 children treated 75 have been returned to school. In Bath also 75 per cent. were able

lines of what Miss McMillan had done for the "under fives" in England. The toast was also briefly seconded by Miss Gertrude Herzfeld. During the dinner a telegram was sent from the assembled council and guests to Miss Eleanor Rathbone, congratulating her on her return at the top of the poll in the Joint Universities parliamentary contest. The annual general and council meetings will be held in Oxford in May, 1932.

After-History of Tuberculosis Cases

The London County Council publishes every year a statement of the after-histories of patients who received residential treatment under its tuberculosis scheme, and were discharged five years previously. It has been possible to trace the after-histories of 3,768 cases of adults who were discharged from institutional treatment in 1925. The results are shown in the following table:

Class	Males			Females		
	No. of Cases	Alive 5 Years after Discharge	Dead	No. of Cases	Alive 5 Years after Discharge	Dead
Pulmonary:		Per cent.	Per cent		Per cent	Per cent.
Sputum-negative...	283	77.0	23.0	250	73.6	26.4
Sputum-positive:						
Early cases ...	155	62.0	38.0	123	61.3	38.7
Moderately advanced	1,264	32.7	67.3	644	27.5	72.5
Advanced ...	550	4.7	95.3	268	2.6	97.4
Non-pulmonary (surgical)	113	76.1	23.9	112	82.1	17.9

Particulars are also given of 582 children discharged from residential institutions after having received at least one period of residential treatment; of this number 215 were pulmonary cases and 367 non-pulmonary. The mortality records show that 155 of the pulmonary cases and 329 of the non-pulmonary were surviving after five years.

Central Midwives Board

At the meeting of the Central Midwives Board for England and Wales held on November 5th, the Standing Committee reported that it had had under careful consideration a summary of the replies from lecturers with regard to the methods of the disinfection of hands and the use of rubber gloves taught by them, and that in connexion therewith it had also considered what instructions (if any) should be given to midwives as to the methods of disinfection of hands and the use of rubber gloves. The Board passed the following resolutions:

That, in view of the fact that the replies indicate that the technique adopted in the various training institutions is very diverse in character, it does not prescribe any uniform method of the disinfection of hands and the use of rubber gloves by midwives. This resolution does not invalidate any instructions given in the rules of the Board or in any memoranda issued by it.

tions that a copy of the foregoing resolution, together with Reports of the summary of the replies, be sent to the measures are Health.

y of the summary of the replies be sent district, for inst lecturers who gave information to the places were treated caching in the matter.

nditions in London,

where the sanitary authorities are the City Corporation, the metropolitan borough councils, and the overseers of the Temple. The Central Public Health Committee of the L.C.C., however, proposes that copies of the notifications of cases of food poisoning to the sanitary authority should be required to be forwarded to the Council within twelve hours of their receipt, for the reason that such cases can properly be dealt with only if the area investigated is not limited by the borough boundaries, so that the Council, if quickly informed, would be able usefully to assist in the investigations, by virtue of its administration over every part of the county. The sanitary authorities will pay the fees to the medical practitioners, and the Council will refund to these authorities the fees paid by them for certificates, of which copies had been supplied. It is also proposed to take power to refuse or cancel the registration of premises used for the preparation of potted and preserved food if the premises are unsuitable.

TEMPORARY TREATMENT WITHOUT CERTIFICATION

SIR,—I sympathize with Dr. Dillon (November 14th) because all that he says of the limitations of the Temporary Treatment Clause of the 1930 Act is true. For practical purposes it is not of much use if it applies to less than 5 per cent. of the admissions—namely, for delirious and utterly confused cases only. No other interpretation can be put on the terms of the Section, and no other was intended by our legislators. While not of extensive or even considerable applicability, the Section is nevertheless an epoch-making advance in a legal sense. It forms the thin end of the wedge, and it is up to Dr. Dillon and other psychiatrists who care for the welfare and happiness of their patients to drive the wedge home by educating the public. Temporary treatment is a great advance on the old method of certification and a magistrate's order, or even on the provisional treatment order recommended by the Royal Commission only five years ago. The Commission, a strong body and not unfavourable to medical views, reported that they doubted if public opinion was ready to countenance a departure from the practice of employing a magistrate, and that, as they were recommending reforms that may be practicable in the immediate future, they came to the conclusion, though not without reluctance, that magisterial intervention was necessary. Within four years of this overcautious and somewhat timorous pronouncement, Parliament passed the Temporary Treatment Clause, doing away with certification and legal intervention in certain cases. This surely marks an epoch from the legal point of view, for which we ought to be grateful.

The provisions of the Temporary Treatment Clause are taken with modifications from the Scottish Schedule G, which was passed in 1857. In Scotland we are able to keep private patients in nursing homes for a period not exceeding six months, and, if necessary, under compulsion, on the recommendation of a doctor, this schedule applies to every private patient whose mental disorder is of recent origin, and who is being treated with a view to recovery—a very inclusive category. These provisions do not, but should, apply to mental hospitals as well as to nursing homes, because the former are under regulation and inspection, and irregularities and neglect are less likely to occur in them than in nursing homes. It is also unfair that the rich should have enjoyed a privilege in Scotland for over seventy years, whereas the poor and those of small means, who must be treated in mental hospitals, should have been deprived of the advantages of this form of treatment during that time.

It should be the object of all interested in the care of the sick in mind to induce Parliament to extend the provisions of the Temporary Treatment Clause, and of Schedule G (with amendment) to all recoverable patients admitted to mental hospitals in Great Britain.—I am, etc.,

University of Edinburgh, Nov. 16th. GEORGE M. ROBERTSON.

SIR,—I write to express my agreement with Dr. Dillon's views. I was physician superintendent at Bethlem Hospital when the Lunacy Act of 1890 came into force. Before that, patients of the private class had been admitted on two medical certificates and the request of a relative and without a magistrate's or justice's order. But the Act of 1890 imposed the latter, and largely increased the red tape working of the hospital.

Since then public opinion has gradually grown against "the stigma of certification," and whereas voluntary boarders were being increasingly admitted to mental hospitals and licensed houses, at last it has become legal for them to be admitted to county and borough mental hospitals as voluntary patients. This is no doubt a step in the right direction. But it had been hoped by those of us who are familiar with the large number of acute and curable cases needing the care and treatment of well-equipped mental hospitals and asylums, that many such patients might be put under care as temporary patients without a magistrate's or justice's order. The Mental Treatment Act of 1930 has, however, imposed the restriction that only a person who "is for the time being incapable of expressing himself as willing or unwilling to receive such treatment" can be admitted as a temporary patient.

It is, of course, a well known fact that many acute and curable cases do not in the early stage recognize their need for special care, and are unwilling to submit to treatment, but as convalescence approaches they begin to realize that they were unfit to care for themselves and in the end are very grateful for what has been done for them. Such cases are still, therefore, obliged to be certified, and a reception order must be obtained, although they may need only temporary care. It seems a great pity that such cases cannot be admitted as "temporary" patients. At present only the extreme confusional or stuporous cases can be so admitted, and if they pass out of this stage and become restless and discontented ("the stage of discontent") they must, after a short time, be certified, and a reception order be obtained. I am sure the Senior Commissioners of the Board of Control must recognize that this is a blot on the Mental Treatment Act, and we must hope for an amendment Act before long.—I am, etc.,

London, W.2, Nov. 16th. R. PERCY SMITH, M.D., F.R.C.P.

BRILL'S DISEASE AND TYPHUS

SIR,—The case reported by Dr. Rood-Jones in the *Journal* of November 14th is interesting, but why has it been labelled "Brill's disease"? It does not appear to have exhibited any of the symptoms of that disease except pyrexia and the Weil Felix reaction. The diagnosis was, in fact, based on that reaction. I understand that the case was one of a mild epidemic of influenza. Was the blood of any of the other patients examined for the Weil Felix reaction? For I venture to ask: May not a positive Weil Felix reaction be found occasionally in cases which are not typhus, just as the Widal reaction may occur in a case which is not enteric?

Dr. Brill admitted that the cases he described were not to be distinguished from classical typhus in respect of their symptoms. But he was impressed by the facts that none were fatal and that there was no evidence of contagion amongst them. Curiously enough, Brill, while emphasizing the latter point, entitled his paper "An acute *infectious* disease of unknown origin" (the italics are mine).

The so-called "tropical" typhus was also separated from classical typhus by its mildness and apparent non-infectivity. But Fletcher and Lesslar, who first drew attention to it, admitted that as regards the symptoms it could not be distinguished from classical typhus. Yet since they first described it in the Federated Malay States the disease has become as fatal there, if not more so, than classical typhus used to be in England. During the year April 1st, 1930, to March 31st, 1931, there were notified in those States 106 cases with fourteen deaths, which gives a fatality of 13.2 per cent. I may add that fatal cases of Brill's disease have been observed to occur in the United States of America. Since typhus ceased to be epidemic or endemic in London, isolated cases have from time to time appeared in that city.

May I take this opportunity of drawing the attention of those who are interested to another question—namely, What value is to be attached to the figures of the notifications and deaths in various diseases which appear in the Monthly Epidemiological Reports of the Health Section of the Secretariat of the League of Nations? The typhus returns for the Federated Malay States are a case in point. They were first given in No. 119 (October 15th, 1928). They related to notified cases dating back to the second quarter of 1927. I have extracted the figures as they are given in the Monthly Reports from No. 119 onwards, and from them it appears that there were no cases during the last three quarters of 1927, and only one during the year 1928. Yet according to a table given on page 479 of No. 133 (a number which contained a special article on typhus), confirmed by a statement made on page 493, there were eighty-four cases notified during 1927, and fifty-seven during 1928. It is disconcerting to find such discrepancies in an official publication of so important a body as the League of Nations. I may add that I received private information a year or two ago that the League's returns relating to small-pox in a certain African territory were by no means to be relied upon.—I am, etc.,

West Hampstead, N.W., Nov. 16th. E. W. GOODALL.

"WHAT IS LIFE?"

SIR,—I have tried to point out in my little book, the *Philosophy of a Biologist*, that loss and replacement ceaselessly go on, both in living and in dead substances. If the organisms of a species show individualism, so do atoms; chemical and physical constants are merely statistical averages of an infinite number of individuals summarizing a variable population. Atoms, no less than organisms, may retain their identity in spite of ceaseless change; each instant activity of either atom or living cell is creative; the identity swings about a mean and is never the same for two moments. To the claim that "there is present in the living thing an active principle organizing it to carry out a set of self-interested purposive actions" science answers: Can we deny self-interested purposive action to the spontaneous emission of alpha particles from radium and the play of protons and electrons? Professor Haldane himself has said that "modern physical investigation of the atom and molecules seemed to be endowing them with something very like an individual life." Each atom of a crystal or of a drop of water is complex, active, evolving, unknowable in ultimate nature as is a living cell. Progress is made and tested by experimental operations, and theory based on operation and observation has led astronomers, physicists, and biologists over and over again to fresh operation and observation and to new discovery. Let us, while reverencing the infinite unknowable "power behind the sun," get on with our operations and observation which yield fruitful results alike for dead and living substances.—I am, etc.,

LEONARD HILL.

INJECTION OF LIPIODOL

SIR,—I can fully endorse Messrs. Philip Franklin and Alexander Orley regarding the advantages of their method of injecting lipiodol into the bronchi (November 7th, p. 847). When watching Mr. I. W. Magill administer an intratracheal anaesthetic on one of the patients I was struck by the ease with which he introduced a soft catheter into the trachea, via the nose, without any apparatus or preparation, except spraying the nasal passage and pharynx with cocaine solution. For the past three or four months I have been using this method for introducing lipiodol, and my house-physician, Mr. N. S. Plummer, has also used the method on a number of patients at Guy's Hospital. The method has proved easy and successful in dealing with men, but we have found it more difficult in the case of women, and have once or twice failed, probably because the passages in their upper respiratory tracts are smaller. In general, I find that this method causes the patient less discomfort and tedium than any of the others that I have employed. —I am, etc.,

London, W.1. GEOFFREY MARSHALL.

TOXINS AND ENZYMES

SIR,—In Dr. Woodcock's interesting letters on the distinction between toxins and enzymes a definition of a "true toxin" is attempted. In his letter published on October 17th a "true toxin" is described as "poisonous" and "deadly," and the further statement is made that a toxin cannot be regarded "as imposing an altered mode of functioning upon a cell; it just poisons it, kills it, and that is the end." This rather arbitrary summing-up leaves us still unenlightened as to the mode of death of the cell. If the inquest on the cell is pursued a little further, fresh light is shed on the relation between toxins and enzymes.

Coca (*Journ. Infect. Dis.*, 1915) has shown that the haemolytic toxin of cobra venom is a fat-splitting enzyme—a lipase. This lipase breaks up the lecithin of the red blood corpuscle into oleic acid and desoleolecithin; both these substances disrupt the blood cell. Dr. Woodcock suggests that bacteriolysin may be classed as an "abnormal" enzyme. It may be claimed that toxins can also be grouped under the heading of enzymes, their peculiar or "abnormal" feature being the production of antibodies when injected into animals. Anti-enzymes as well as antitoxins exist naturally; witness the antitrypsin in normal serum. There is some evidence that anti-enzymes appear after the injection of enzymes into animals (Luers and Albrecht, 1926), but the work is not accepted as free from error by Haldane (*Enzymes*, p. 165).

Locke and Main (*Journ. Infect. Dis.*, 1931) have pointed out that selective specificity is characteristic of both enzymes and toxins. They have demonstrated the resemblance between the properties of neurotoxin, oxidase, and erepsin on the one hand, and haemotoxin, dehydrogenase, and papain on the other. They have also shown that some bacterial toxins may owe their poisonous characters to their copper-carrying respiratory enzyme,

which proves intolerable to the cells in the more highly organized aerobic tissues into which the toxins diffuse (*Journ. Infect. Dis.*, 1930). As knowledge of the mode of action of the toxin increases, the resemblance to enzyme action becomes more apparent.

A very large number of chemical substances may depress the action—that is, poison an enzyme—and among them surface-acting substances such as substituted urethranes (Haldane) This may be the rationale of the use of S U P and S U.M. 36 and 468 by McDonagh (*Nature of Disease*, vol. II). The claim is made that these drugs do not kill the invading organisms, but that they increase the resistance of the patient. On the other hand, it is equally possible that they depress the activity of the enzymes or toxins of the invading organism.—I am, etc ,

FRANK BODMAN.

Bristol, Nov 8th

LOCKED TWINS

SIR,—I had recalled to me, a few days ago, a neglected duty, that of reporting a rare and interesting case, which I attended several years ago. It was a case of twins, where the registrar of births doubted the parents' statement that neither child had priority of birth. I have full notes of the case, and, as it has not lost its interest, I hope you will find space to publish it.

On the afternoon of February 21st, 1924, I was called to Mrs C , who was in labour at full term. She was a healthy, well-built young primipara, with a muscular abdominal wall and a roomy pelvis The os admitted two fingers, the membranes were intact, and a head was felt about to engage, the anterior fontanelle to the right posteriorly Just at this point my fingers touched something that felt like a loop of cord within the membranes On my pressing this against the skull it was suddenly withdrawn and I concluded it was a hand. This constituted the only worry I had about the case when I left it in the hands of the midwife, with instructions to report any unusual happening

Several hours afterwards I was called urgently by the nurse and was astonished to find her pulling on the legs and body of a breech case. My next surprise was that, though the body looked small and limp, it gave such a sense of rigid union with the mother's body that I immediately desisted At a glance it was very striking how tightly the shoulders were pressing against the upper part of the vulva, so that they could not be drawn away from it or towards the perineum the neck passing close up from behind the symphysis There was no bulging of the perineum. On inserting my fingers I found, midway up in the pelvic canal, a small, firm head, lying almost in the second position. For convenience in description the infants may be called No. 1, the first seen, and No 2. Traction on No 1 made no impression on No 2.

After waiting over twenty years I had come up against my first case of locked twins. My long wait was not surprising, for, on inquiring, I found that this complication had come to be looked upon as a myth in at least one large maternity hospital, no cases having been recorded for very many years.

The question now arose how I was to deal with it. Of treatment, all I could remember was that amputation of No 1's head would probably become necessary. I presumed, however that that would be only after simpler measures had failed Why not try traction with forceps on No. 2's head, There were indications for doing so. The head of No 2 was small , so also, probably, was its body. There was room in the pelvis for No. 2's head and No. 1's neck ; so, also, should there be room for No. 2's body and No. 1's neck No 1's head appeared to be at the pelvic brim, and so probably capable of being displaced to let the other's body pass as it could not be if it were well engaged in the pelvic canal So the most reasonable thing to do would be to hold No 1's head *in situ* and make traction on No 2's shoulders tightly against the symphysis, without much difficulty No 2 came away, its feet accompanied by No 1's head, so that I could not give either the priority of birth. It was virtually, though not actually, a case of *neck and neck*

The midwife a lady of long experience, was astonished to see a child born apparently before the one she had been making traction on so long

Both infants looked inanimate, and No 1 being considered hopeless from the first, all the efforts at resuscitation were applied to No 2. After a short time it breathed but most surprising of all, No. 1, who had been being meanwhile uncared for, began to make feeble inspiratory efforts, and in about half an hour was breathing well

The infants were females, in a common sac with united placentæ Their weights were, No 1 3¼ lb , No 2 a little over 3 lb Both came away considerably below Both did well for about two months, when the bigger, No 1 died of an acute bronchial trouble.

Reviewing the case, on my first examination it must have been No. 1's foot I felt behind and to the right of No. 2's head. Where, how, and when the body passed the head and then slipped round in front I am sorry I was not there to see , but the nurse reported that it was a head presentation till shortly before she had had to send for me My opinion was that uterine contractions had been feeble till the parts had become relaxed, and then, with strong pains, the complication had developed rapidly, owing to the wedge action of the feet and legs passing behind the head No doubt No 2's head was pushed aside while the body passed, and, later, interlocking of the heads had caused No. 2's head to be pulled down into the pelvis. Other factors which helped to bring about the complication were, the roomy pelvis, the small heads, the common sac, and pulling on No. 1 Naturally, at the point where the uterine efforts or traction caused the upper head to press the lower against the hollow of the sacrum instead of in the axis of the pelvis, the normal mechanism of labour was defeated

It may be said that this was not really a true case of impacted twins, because only one head could be said to have been in the pelvic canal It was truly a case of locked twins, and, certainly, decapitation would have become necessary if I had persisted in trying to deliver No. 1 first Supposing I had found both heads in the pelvic canal, I think I should have employed the same treatment, with the modification that I should have encouraged No 1's head to follow No 2's, my reason being that, the pelvis being capable of containing both heads and necks, the outlet, unless abnormally contracted, ought to let them through. In such a case, of course, No 2's head would be so near at hand, distending the perineum, that it would be calling for traction.

Besides contracted outlet there is another condition that might render delivery without decapitation impossible, and that is, if No. 1's head has partially entered the pelvis but is too big fully to enter with the other child's neck. It is extraordinary, however, how pliable, extensible, and compressible the human newborn infant is, and, as the heads are compressing one another in a manner unfavourable to delivery, it is surprising what a little traction might do to relieve this.—I am, etc ,

ALEX. MACINTYRE, M B , Ch B

Airdrie, Lanarkshire, Oct. 31st

DIET AND PUERPERAL SEPSIS

A Farmer's Observations

SIR,—I read with great interest the article entitled "Diet as a prophylactic agent against puerperal sepsis" in the *Journal* of October 3rd, and thought that perhaps the work and observations of a farmer patient of mine might be of interest

He told me that he had been reading an article in the daily paper and had no idea that puerperal fever was so common among women, and also that doctors seemed surprised that so few cases occurred in slum districts, but

that that was just what he would expect. He went in for breeding pedigree stock, and twenty years ago he found that at the end of nearly every season he lost one or two ewes as the result of puerperal fever; sometimes he would lose five or six, occasionally none, but the deaths always occurred towards the end of the season. Later he began to lose them earlier in the season, and the numbers lost became much greater, so much so that the outlook became alarming, and as many as 60 per cent. died.

He consulted many veterinary surgeons, and all advised that the lambing pen should be changed. But my farmer friend would not agree to this. He had already carried out various experiments, which seemed to prove to him that infection was not the cause, or at any rate not the sole cause, of the trouble. In spite of many precautions taken to prevent infection, the mortality had not decreased. He had taken five ewes, a few weeks before 'ambing was due, and put them in a field by themselves. They were left out day and night with no one to tend them, and were allowed to lamb without aid; yet three died as a result of puerperal fever. He had lambed some in a new pen treated with creosote, yet the first ewe to lamb had died.

He gave up all idea of infection being the real cause, and looked about for some other reason, and finally hit upon what he believes to be the solution. Contrary to all advice, he had the courage to test his own convictions, and decided to lamb forty ewes in the same pen in which he had lost some 60 per cent. a few weeks earlier; in this pen there was the same six inches of manure on the floor into which had soaked the discharges from those ewes which had died as the result of puerperal fever. He did not lose a single ewe, though he kept them in the pen for three days instead of letting them out as usual. Since that year he has not lost a single ewe from puerperal fever—that is, for nineteen consecutive years. But during that year he made various experiments. He divided his flock into two groups—treated and untreated—and deliberately tried to infect his treated ones with the lochia of those ewes dying as the result of puerperal fever, but he was unable to do so. He found he could produce the disease when he wished, and stop it when he wished, but he could not cure it when it had once developed. As I have said, at first he usually lost a few cases at the end of each season. Possibly he would start with 100 ewes; each day some would lamb, and so the numbers that remained to lamb would be reduced; yet, roughly, the same amount of food would be given, so that perhaps 50 ewes would be getting just as much food as had been previously given to 100. Deaths then began to occur.

He started to go in for pedigree stock, and was anxious to get fine ewes; the finer the animals he got the more he lost as a result of puerperal sepsis, and he began to lose them at the beginning of the season. He also noticed that those farmers who took great care of their flocks and fed them well lost most ewes. When he cut down the ration he did not lose a single case, but he was keen on getting fine animals, and gradually increased the food until cases of sepsis began to crop up. He next cut down the food, and no more cases occurred. He then deliberately put aside the last five ewes, fed them up well, and lost three. The five put into the field by themselves had to contend with the elements, and were therefore fed very well, and three of them died.

He has convinced himself that the whole cause of puerperal fever in ewes is due to fattening up and overfeeding with artificial foods, such as cake. Natural foods such as hay and turnips do not matter. The treatment, or rather prevention of the disease, is simply starvation, or rather giving a strictly limited ration with natural foodstuffs. He finished by saying: "Of course, doctor, I don't know much about human beings, but it seems to me that in many ways what applies to animals applies very much the same to them, and if it is true that puerperal fever occurs more amongst the well-to-do, and not amongst the poor, then feeding up with unnatural foods may have something to do with it."—I am, etc.,

H. P. Dawson.

Grantham, Lincs, Nov. 3rd.

"FAILED FORCEPS" CASES

Sir,—The account of the 100 consecutive cases after forceps application admitted to the Liverpool Maternity Hospital[1] is a perfect example of how deceptive quite accurate figures can be. There is no indication of whether these cases were admitted in a month or in a year. "In 59 instances the patient was in the first stage of labour, the smallest degree of dilatation being a two-finger os." This gives the impression that in Liverpool doctors are brandishing forceps night and day, and applying them to every undilated os on Merseyside. It is a relief to read further on that only three cases of ruptured uterus were admitted. One had gathered the impression that there is scarcely an unruptured uterus in Liverpool. The paper then goes on to draw conclusions about the inadequacy of midwifery teaching. I suggest that a man who puts on forceps in the first stage is unteachable; why waste the time of the ninety-nine for the unteachable one?

Such statements as these are entirely misleading, because they give only a part of the truth. What percentage of forceps applications in the area served by the hospital do these hundred cases represent? Nobody knows. All that the figures prove is that there are a certain number of medical men in a big city who are unfit to practise midwifery. As this is a self-evident fact, why waste time and paper by going into fantastic percentages?—I am, etc.,

R. W. Cockshut.

Hendon, N.W., Nov. 10th.

TREATMENT OF ANTHRAX BY N.A.B.

Sir,—My statement is from memory, but I think I am correct in saying that Professor Eurich treated anthrax with N.A.B. at Bradford in 1913.

Since Pijper's article in the *Lancet* in 1926, to which Drs. Coghlan and Shorvon refer in the *Journal* of November 14th, there have been two or three subsequent articles on the same subject in the *Lancet*, and also in the *Guy's Hospital Gazette*, which contains yet another account of this treatment in its current number. A reference to the report of the Chief Inspector of Factories for 1930 would show that N.A.B. is widely used in this country for the cure of anthrax.—I am, etc.,

C. G. Brentnall, M.B.,
Physician in Charge of Anthrax Department, Warrington Infirmary.

November 14th.

PAIN IN THE ARM AND A DEAD TOOTH

Sir,—In spite of any appearances to the contrary I did not so much miss Dr. Crookshank's point as feel that it was far from clearly expressed in his first letter. Without this further explanation his advice, if followed, would have led to much unnecessary tinkering with patients. We dare not attempt to put all right that is wrong; sorely tried Nature must be allowed some field for her recuperative activities. Were there more thorough co-operation between clinician and pathologist there might be less reason for the latter to receive the hopeful therapeutic excursions of the former with incredulity.—I am, etc.,

Harold H. Sanguinetti.

Kensington, W., Nov. 16th.

FOREIGN BODIES IN THE ALIMENTARY TRACT

SIR,—After reading Mr. Gordon Bruce's paper in your issue of October 24th, an interesting case came to my mind.

My brother, the late Dr. R. J. Collier of Manor Park, was called in to see a woman who complained of a large painful lump in the right iliac fossa; thinking this was a growth, and considering that the patient was very ill, he called in a surgeon from the London Hospital, who operated pretty soon, I believe. During the operation a hard substance was encountered, and to the great surprise of the surgeon and my brother, a large smoker's knife, with the blade open at a right angle to the shaft, was pulled out. It seems that the woman, in a drunken fit, had tried to commit suicide by pushing the knife down her throat four months previous to the operation; after its perilous journey it anchored at the caecum. I saw the knife some days after the operation, and I believe the intention was to find a place for it in the London Hospital Museum; whether this was carried out or not I do not know. I may add that the patient did not live long after her operation.

—I am, etc.,

Westminster, S.W., Nov. 9th. W. A. COLLIER.

BIOPHYSICS

SIR,—In your issue of October 31st (p. 804), the reviewer of Dr. Wishart's book on *Groundwork of Biophysics* says: "Those portions of the subject [physiology] which are investigated with the aid of exact physical measurements are now often called biophysics." In June, 1930, the Society of Apothecaries published the first official *Register of Bio-Physical Assistants*, at the instigation of the British Medical Association at its Annual Meeting in 1929. If the term "biophysics" has the meaning which your reviewer suggests, then the official *Register of Bio-Physical Assistants* is totally misleading, and it is obvious that either the Society of Apothecaries must claim precedence in choosing this term or else change the title of these assistants in physical medicine. Personally I should prefer the latter course, since the term "bio-physical assistants" does not convey, to the ordinary medical man, the real nature of the work undertaken by these assistants. The whole nomenclature of physical medicine needs overhauling, and it is time some authoritative body undertook this.—I am, etc.,

R. KING BROWN,
Editor, British Journal of Physical Medicine

London, S.E.5, Nov. 12th

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons this week carried a financial resolution authorizing the introduction of the Abnormal Importations (Customs Duties) Act. The Government proposed to carry this Bill into law during the week.

The Parliamentary Medical Committee arranged to hold its first meeting on November 18th, and to dine together that evening.

The Minister of Health and the Secretary for Scotland have now presented a resolution explaining the proposed resolution prolonging the health insurance of genuinely unemployed persons.

Social Services

During the debate on the Address in the House of Commons Sir STAFFORD CRIPPS, for the official Opposition, moved an amendment, on November 12th, which ended by expressing regret that there was no mention in the King's Speech of any intention to restore and develop the social services.

Speaking against the amendment, on the same day, Dr. F. E. FREMANTLE said that Conservatives could share the feeling expressed in the last words of the amendment. They had to maintain the social services in a time of fluctuating money exchanges and price levels. They must maintain the efficiency of institutions and personnel. They must make better use of what they had, and must progress slowly but surely. They wanted to feel sure of a general countenance of the movement for housing the people, but with a stop in the waste that had been going on. With all the £12,000,000 a year for housing subsidies with which the Exchequer was saddled for the next forty or fifty years there had been little or no improvement in the housing of those who could afford only to pay 10s. or less a week in rent. Parliament must stop subsidizing people who could build for themselves and focus attention on slum clearance and the building of houses at lower prices. He thought they could expect the Town and Country Planning Bill to be put into law, with the necessary amendments, very soon. The country required less costly administration in some of its institutions. The Board of Control lately made an excellent report on their permanent institutions, especially those for mental defectives. They had learnt from foreign countries. There was extravagance and unnecessary expenditure in these institutions. The whole trend of medical and surgical science of recent times had shown they could get on better with cheaper material. There was enormous waste in the building and furnishing of present institutions. They did not want things that would last for a hundred years, nor marble corridors, but cheaper, and at the same time good, building. They must maintain the efficiency of the institutions and of their personnel. Whatever Parliament did, it must keep its hands off research. He hoped the scheme of veterinary research would be brought to fruition. The Local Government Act, 1929, had caused tremendous developments, and a breathing space for a year or two would be good for local administration. If instead of passing new legislation and setting up new officials they got down to the proper administration of that Act, local authorities could progress without further expenditure. Dr. Fremantle asked the House to consider the institutions under the Ministry of Pensions, which were becoming obsolescent. The number of persons dealt with by the Ministry of Pensions was shrinking, but another Department was building new hospitals and setting up new staffs. Much could be done if they got the medical departments of the different Ministries to co-operate. He emphasized the great value of voluntary institutions in addition to official institutions. Large spheres had up to now been most usefully covered by voluntary institutions and services, the hospitals and the nursing services were two instances. They should develop them. People should be taught that they must help themselves if they were to get full value from the opportunities which were provided. As long as the amount of good done was measured by the amount of money spent, so long would people of all classes be diverted from the parts they should play.

Miss CAZALET said that she entirely agreed with what Dr. Fremantle had said last week in regard to housing. Although we were spending more than £12,000,000 in subsidies we were not meeting the needs of those who could only afford 5s., or at the most 7s. 6d., for their weekly rent. A far simpler form of flats and tenements ought to be constructed if the immediate needs of the poorest citizens were to be met. With the co-operation and consent of the Ministry of Health a great deal more could be done in this direction and she urged the Minister of Health to consider the question very carefully at the earliest possible moment.

Excessive Imports

On November 16th Mr. RENDALL, speaking on the Government's proposals for dealing with excessive imports, said that during the last few weeks there had been anticipations abroad that the imposition of customs duties might be part of the policy of the Government. The result had been that clever folk abroad had been trying to get their imports into this country. In the opinion of the Government too much had been done to an excessive amount. Such imports included knives and surgical instruments. The Government had come to the conclusion that the best way to deal with this abnormal

importation, and at once, was to give the Board of Trade power to issue an Order which would impose a duty, not exceeding 100 per cent., on the value of the articles. It was hoped that a Bill authorizing this would be passed through all its stages and receive the Royal assent on November 20th. The powers which were being asked for were emergency powers, and the Government's proposals must come up for consideration again in six months, or something else must take their place.

The motion for the Address was carried without a division.

Mr. HORE-BELISHA, replying to Sir H. Page-Croft on November 16th, said that for the ten working days ended November 10th last the value of imported chemicals, drugs, dyes, and colours was £895,399.

Highbury Pensions Hospital

Replying to Mr. Crooke, on November 12th, Major TRYON (Minister of Pensions) said that, owing to the steady decline in the number of patients in the Highbury Hospital, Birmingham, it had been decided, in agreement with the hospital committee, that the maintenance of this institution as a Ministry of Pensions hospital could no longer be justified. It would be closed at the end of December. The number of men still requiring institutional treatment at the end of the year would be small, and treatment would be given them in a Ministry or in a civil hospital. They would enjoy the same privileges as other pensioners undergoing treatment in those institutions. Dr. FREMANTLE asked whether any use was to be made of Highbury Hospital, or whether it would be shut down and its value thrown away, when so many hospitals had to be built. Major TRYON asked for notice of this question.

Foot-and-Mouth Disease

On November 16th Sir J. GILMOUR, replying to Mr. Hurd, said that he had considered the latest report of the Foot-and-Mouth Disease Research Committee as affecting the risks involved in the importation of dried milk and other milk products from foreign countries where disease was prevalent. While it would appear from the laboratory experiments so far conducted that milk powder, in common with many other commodities, might be a potential carrier of foot-and-mouth disease, it had not been demonstrated that the virus survived in milk powder under trade conditions. The practicability of carrying out further tests under trade conditions was under consideration.

Unemployed Insured Persons.—In reply to Mr. Rhys Davies, on November 12th, the Minister of Health, Sir E. HILTON YOUNG, said he proposed to introduce immediate legislation to protect the health insurance and pension rights of those unemployed insured persons who would otherwise lose these rights at the end of the year.

Housing.—Sir E. HILTON YOUNG informed Dr. F. E. Fremantle, on November 12th, that 618,547 houses had been built in England and Wales by local authorities from 1919 to September 30th, 1931. Approximately 1,135,000 houses had been built by private enterprise during the same period.

The Services

DEATHS IN THE SERVICES

Deputy Inspector-General Henry Laurence Crocker, R.N. (ret.), died recently at Plymouth, aged 79. He was educated at University College Hospital, and took the M.R.C.S. in 1875 and the L.R.C.P.Ed. in 1876. Entering the Navy as surgeon on March 31st, 1876, he attained the rank of fleet surgeon on September 5th, 1893, and retired, with an honorary step in rank, on June 1st, 1906. He was granted a Greenwich Hospital pension in 1915.

Colonel William Mitchell Houston, I.M.S., died on October 30th in King Edward's Hospital for Officers, Osborne, Isle of Wight. He was born on November 2nd, 1875, and was educated at Trinity College, Dublin, where he graduated B.A. in 1897, and M.B., B.Ch., and B.A.O. in 1899. Entering the I.M.S. as lieutenant on June 28th, 1900, he attained the rank of colonel on August 7th, 1929. He served in Somaliland, East Africa, in the campaign of 1903-4, receiving the medal with a clasp. On the outbreak of the great war he was appointed to the staff of the Indian hospital ship *Gurkha*, which was engaged in carrying Indian and Australian wounded from France and the Dardanelles to England. In 1915, when arrangements were being made in India to cope with the large contingents of wounded then arriving from Mesopotamia, he was recalled to India to serve as registrar of the Victoria War Hospital, Bombay, and the following year he was appointed officer commanding the Officers' Convalescent Home, Nasik. Thereafter he served as health officer of the Port of Bombay, until his appointment in 1929 as Inspector-General of Civil Hospitals, Bihar and Orissa, an appointment which he had to relinquish in December owing to ill-health. Colonel Houston had the honour of being appointed honorary surgeon to the Viceroy, in May, 1929.

Lieut.-Colonel Paul Knighton Gilroy, *M.C.*, Indian Medical Service, died after a long illness on October 22nd, aged 46. He was born on June 7th, 1885, and was educated at Emmanuel College, Cambridge, and at St. George's Hospital. He took the M.R.C.S. and L.R.C.P.Lond. in 1909, and graduated as B.A. (with honours), M.B. and B.Chir.Cantab. in 1910, and as M.D. in 1913. After filling the post of house-physician at St. George's, he entered the I.M.S. as lieutenant on January 29th, 1910, and became lieutenant-colonel on July 29th, 1929. He served in the war of 1914-18 in Iraq, 1915-18, was mentioned in dispatches in the *London Gazette* of June 15th, 1916, and March 12th, 1918, and received the Military Cross on January 1st, 1918. At the time of his death he held the appointment of superintendent of St. George's Hospital, Bombay.

Lieut.-Colonel William Lapsley, O.B.E., of La Porte, St. Jacques, Jersey, died there suddenly on October 21st, aged 56. He was born on July 28th, 1875, educated at Queen's College, Cork, and graduated as M.B., Ch.B., and B.A.O. of the Royal University, Ireland, in 1899, and afterwards took the D.T.M., with distinction, at the London School of Tropical Medicine, in 1912. Entering the I.M.S. as lieutenant on June 28th, 1900, he became lieutenant-colonel on December 28th, 1919, and retired on July 24th, 1928. He served in the Waziristan campaign on the North-West Frontier of India in 1901-2, gaining the frontier medal with a clasp; and in the war of 1914-18; in Persia in 1918-19, when he was mentioned in dispatches in the *London Gazette* of February 3rd, 1920, and received the O.B.E. on June 3rd, 1919.

Universities and Colleges

VICTORIA UNIVERSITY OF MANCHESTER

Dr. E. H. Walker has been appointed Lecturer in Public Health Administration.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

An ordinary meeting of the Council of the Royal College of Surgeons of England was held on November 12th, when Lord Moynihan, the President, was in the chair.

Diplomas of Membership were granted to 122 candidates who had passed the examination in medicine, surgery, and midwifery of the Examining Board in England.

Diplomas in Public Health were granted jointly with the Royal College of Physicians to nineteen successful candidates.

The lists of successful candidates for the diplomas of Membership of the College and in Public Health were printed in the report of the meeting of the Royal College of Physicians published in our issue of November 7th (p. 876), with the exception of H. K. G. Nash and Marie W. E. H. Schuyt van Castricum, who were granted the diploma of Membership.

It was reported that two candidates had been successful at the Primary Examination for the Fellowship held at Toronto in October.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At the meeting of the President and Fellows held on November 6th, the following Members of the College were admitted to the Fellowship: Daniel Moriarty, Robert Henry Joseph Mulhall Corbet, Gerald Spence Smyth, Henry Francis Moore. Yang Lin was admitted as a Member and Licentiate of the College.

Obituary

BILTON POLLARD, M.D., F.R.C.S.

Consulting Surgeon, University College Hospital; Emeritus Professor of Clinical Surgery, University College, London

Mr. Bilton Pollard, whose death at Bournemouth on November 5th we announced in our last issue, spent the greater part of his professional life in close association with University College Hospital and its medical school. Since his retirement from practice seventeen years ago he had rather lost touch with the medical world of London.

Bilton Pollard was born on November 11th, 1855, at Rastrick in Yorkshire, where his father, Tempest Pollard, M.R.C.S., was in general practice. From Epsom College he went to University College, London, in 1874, and gained first class honours in the intermediate and final examinations for the M.B. degree of London University. He obtained the M.R.C.S. diploma in 1879, graduated M.B. and B.S. in 1880, and became M.D. and F.R.C.S. in 1881. For a year he was demonstrator of anatomy at University College under Professor Thane, having Rickman Godlee and Quarry Silcock as his colleagues. In those days a young surgeon in London had very slight opportunities for operating, even when on the staff of a hospital. Pollard accordingly went to Manchester, and gained his early experience as resident surgical officer at the Royal Infirmary; he then returned to University College Hospital as surgical registrar. From 1885 to 1897 he was surgeon to the North-Eastern Hospital for Children (now known as the Queen's Hospital) in Bethnal Green. He was elected assistant surgeon to University College Hospital in 1887, was promoted full surgeon in 1894, and two years later became professor of clinical surgery at University College. On his retirement from the active staff in 1914 he was elected consulting surgeon and emeritus professor.

Bilton Pollard.

As an operator Pollard was deliberate, but he was very sure and safe, his colleagues knew this, and often asked for his services for themselves and their families. As a teacher he took great pains, never allowed himself to be hurried, and was always willing, and indeed anxious, to help students. Thus he acquired a great reputation among University College Hospital men, and built up a considerable practice. Before a special department was formed, he was in charge of ear and nose cases at the hospital. At various times he acted as examiner in surgery in the Universities of Oxford and Manchester; he was for ten years a member of the court of examiners of the Royal College of Surgeons of England, and from 1910 to 1918 he served on the Council.

As surgical registrar in the early 'eighties Bilton Pollard was responsible for four issues of the University College Hospital surgical reports, and he contributed papers on surgical subjects to this and other medical journals. Outside his own hospital he was perhaps best known to students as editor of the twelfth, thirteenth, and fourteenth editions of Christopher Heath's *Minor Surgery*. Apprehensions about his health led him to retire from practice earlier than most surgeons, and he went to seek quiet life on the south coast, living first at Sidmouth, and later at Bournemouth.

We are indebted to Mr WILFRED TROTTER, F.R.S., for the following appreciation:

Bilton Pollard was the last survivor of four men who, in the early years of this century, gave a special quality to the surgery school of University College Hospital. The others were Arthur Barker, Rickman Godlee and Victor Horsley. Barker was perhaps the most elegant surgical technician of his time. Godlee was an anatomist, an artist, a scholar and a surgeon of great ability in the best academic tradition. Horsley was an acknowledged genius, in whose company even the most obtuse could not miss the thrill of contact with great powers. In this very distinguished group Pollard easily held his own as an influence and a force. He was no virtuoso of the operating theatre, he was no profound scholar, he had opened up no new province of surgery, but he was a complete practical surgeon armed in every branch of the art, and the confident master of his equipment. If the light he shone with was relatively mild, it was also supremely constant and without those intermittences which seem to be unavoidable by great brilliance.

To the superficial his practice might have seemed wanting in animation and vigour, for he came to a decision slowly, and he was one of the most deliberate operators of his generation. He has been known, at the end of an operation, when all his assistants were sinking with fatigue, to take down an elaborately completed line of suture because, after long and placid contemplation, it was found not to reach his standard of the exact and safe. His methods, however, as a whole must have been in fundamental harmony with the needs of the living body, for his patients commonly behaved in a way not always shown by those of more dashing operators, in promptly getting well. The degree and the consistency of his practical success found their most solid testimonial in the fact that he early became the students' surgeon, and it was to him that they brought their mothers and their aunts, knowing that they would find him as sure and realistic in diagnosis as he would be competent and determined in treatment.

Pollard's whole career was an exemplary demonstration of the familiar truth that for effective use in every so technical an art as surgery character can contribute as

much as, if not more than, aptitude. He was a Yorkshireman, and to the attentive ear his native county lingered faintly and pleasantly in his speech. His figure was sturdy and comfortable, his expression was mild and benevolent, but with a straight look that showed he could be resolute and formidably direct. When reproof was necessary he had the admirable art of giving it weight without anger, so that it did its work and left no by-product of bitterness and discouragement. His mind was shrewd and realistic rather than actively intellectual, and he had an implacable good sense that no ingenuity could delude. His strongest personal characteristic was his rock-like placidity. This was no mere inertia, but an inward calm in which the perplexities of diagnosis were surprisingly often resolved, and which made him as an operator extraordinarily independent of his audience, and unruffled by complications. His serene temperament was undoubtedly the very substance of his being, and in the last analysis the quality that put him among the very small band of the soundest, the most uniformly successful, and, above all, the most trusted surgeons of his time.

ROBERT ALEXANDER MURRAY, M.D., C.M.

Consulting Surgeon, Stockport Infirmary

We regret to announce the death, on October 4th, of Dr. R. A. Murray, who for the last fifty years had been one of the most prominent personalities in Stockport.

Robert Alexander Murray was born in 1858, and received his medical education in Edinburgh and Paris. He graduated M.B., C.M.Ed. in 1879, and proceeded M.D. in 1893. He was appointed house-surgeon to the Stockport Infirmary at the age of 22, and six years later was elected honorary surgeon. For twenty-five years he served the institution in this capacity, and when he retired as senior surgeon in 1912 he continued to act as vice-president of the board of management, and was appointed honorary consulting surgeon. He conducted a large private practice without specializing in any one direction. With the outbreak of war he devoted his energies to the treatment of the wounded, and it was largely due to his influence that several of the fine new schools which had recently been erected in Stockport were placed at the disposal of the military authorities for use as hospitals. He was in a great measure the author of the scheme whereby these schools, together with the town hall and other buildings, could be most advantageously employed. He became the principal medical officer of the local military hospitals, and in recognition of his services received the O.B.E. When Brinnington Manor was taken over by the British Red Cross Society as a neurological hospital for shell shock cases Dr. Murray was appointed its consulting surgeon; he also acted as medical referee for the War Pensions Committee.

For twenty-seven years Dr. Murray had been a member of the Stockport Town Council, and in 1920 was appointed alderman; he was chairman of several committees, and associated himself particularly with the improvement of sanitation in the erection of public buildings. He was a senior magistrate in the town, having been appointed in 1892. He was the governor of several educational institutions, and a member of the court of governors of the University of Manchester. For nearly fifty years he played a leading part in electoral campaigns as a prominent Conservative, being chairman of the Stockport Conservative and Constitutional Association from 1910 to 1926; on relinquishing that position he became president. He was a member of the British Medical Association, and of the Chester, Lancashire, and Stockport Panel Committees.

America has recently lost another eminent obstetrician in Professor JOHN WHITRIDGE WILLIAMS of Johns Hopkins University, Baltimore. He died on October 23rd, the very day on which, had his health allowed him to travel to England, he was to have received the Honorary Fellowship of the British College of Obstetricians and Gynaecologists. Through his classic textbook Professor Whitridge Williams was probably better known than any other English-speaking obstetrician, and his death, coming so soon after that of Professor Polak, is a heavy loss to obstetrics and gynaecology in America, and indeed throughout the world.

The death of EDWIN MORTON, M.D., at the age of 68, leaves a gap in the medical life of Oxford which it will be hard to fill. A graduate in medicine of Edinburgh, he took his M.A. at Oxford and the D.P.H. of the R.C.P.S.I. After some years of general practice in Redditch and Woodstock he became assistant school medical officer for Oxfordshire in 1908, and medical officer of health for North Oxfordshire combined districts in 1912. After taking this public appointment his interest in the clinical side of medicine remained as keen as ever. He was a regular attendant at meetings of the Oxford Medical Society, and was always ready to discuss modern ideas and methods. As an M.O.H. he was always intensely alive to the position of the general practitioner, and showed much kindness to newcomers to his area. Dr. Morton's interest in Oxford, and particularly in his old college, Christ Church, was one of the marked features of his life, as were his sense of humour and his unfailing tact and courtesy the keynotes of his association with his fellow practitioners.

Medical News

The Purvis Oration before the West Kent Medico-Chirurgical Society will be given by Sir William H. Willcox at the Miller General Hospital, Greenwich, on Friday, December 11th, at 8.45 p.m.; the subject will be recent researches into the causation of chronic rheumatism.

At the meeting of the Medico-Legal Society to be held at 11, Chandos Street, W.1, on Thursday, November 26th, at 8.30 p.m., Dr. Emanuel Miller will read a paper on the social aspects of juvenile delinquency, to be followed by a discussion. The annual dinner of the society has been indefinitely postponed.

At the next meeting of the Society for the Study of Inebriety, to be held in the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W., on Tuesday, January 12th, at 4 p.m., Dr. W. Norwood East, H.M. Commissioner of Prisons, will open a discussion on mental defectiveness and alcohol and drug addiction.

The autumn dinner of the Irish Medical Schools' and Graduates' Association will be held in the Georgian Suite, Piccadilly Hotel, on Thursday, November 26th, at 7.45 p.m., with the president, Mr. Andrew Fullerton, F.R.C.S.I., in the chair. The High Commissioner for the Irish Free State and Dr. W. G. Willoughby, President of the British Medical Association, will be the official guests. Dinner tickets, for members and guests, ladies and gentlemen, 15s. 6d. (exclusive of wines). Application, accompanied by remittance, together with names of guests, should be forwarded as early as possible to Mr. James Carver, F.R.C.S., St. George-in-the-East Hospital, E.1.

The annual dinner and dance of the British Serbian Units Branch of the British Legion will be held at the Lysbeth Hall, Soho Square, W.1, on Saturday, December 5th, at 7 for 7.20 p.m. The president, Miss Marx, will be in the chair.

whole matter dealt with as if the practice had ceased on June 31st, 1931, and started afresh the following day. This might involve altering the assessment for 1930–31 as well as for 1931–32, and, presumably, has not been desired by some, or all, of the individuals affected. Assuming that the gross assessment for 1931–32 is not to be adjusted in this manner, it will hold good as an assessment on the income of the practice for 1931–32, although, in fact, that income has been measured by the amount of the net profits of the practice for 1930–31. The only adjustments arising out of the change will be those necessary because (*a*) Dr. S. will be liable on three-twelfths only of what would otherwise have been his share of the assessment, "X Z" being liable for the remaining nine-twelfths, and (*b*) this may necessitate some change in the personal allowances to be deducted in calculating the tax payable. We suggest that "X Z" writes to the inspector of taxes stating the date of change, and asking him to send a statement setting out the adjustments made and the tax to be paid by each individual in the new circumstances. This statement should then be forwarded to Dr. S. to agree to his share of the 1931–32 tax.

Assistant: Reduction in Earnings

"H. L." was employed up to May 16th, 1931, at £452 per annum, of which £52 was in respect of the expense of using his own car. Since then his gross remuneration has been reduced to £430. What is his liability?

*** The basis of liability is the income of the previous year—that is, 1930–31. But if "H. L." was then employed elsewhere at a rate of remuneration different from that in his subsequent post we consider he would be entitled to depart from the previous year's basis, and be charged for the first year of his new employment on the basis of his earnings for that actual year. Neither the cost of removal nor the expense of his wife's operation would be deductible for income tax purposes. With regard to the amount included in the gross remuneration for professional expenses which he incurs, either "H. L." should be allowed a deduction for his actual expenses, or the "expense" element in the gross remuneration should be ignored. The latter is the correct procedure if the arrangement was in fact to pay £400 as salary and £52 (or £30) towards his expenses of working as an assistant.

Fees for D.P.H.

"P. H." has spent various sums in class and examination fees to obtain the Diploma of Public Health, as he intends to enter the Public Health Service. Can he claim any deduction for the amounts so expended?

*** No. From the fiscal point of view these expenses represent capital outlay to obtain further qualifications, and not expenses incurred in carrying out the duties by which he has been earning his income.

LETTERS, NOTES, ETC.

Phimosis and Circumcision

Dr. J. B. Jessiman (Malvern Link) writes: Truly the path of those who favour, and are courageous enough to advocate, prophylaxis is a difficult and uphill one. The darkness of destructive criticism all but engulfs us, whilst constructive criticism, like Shakespeare's little candle, throws its beams far and wide. The opponents of circumcision seek to confuse a clearly cut issue with their selfish sentimentality, with their empty catch-phrases, such as "barbarous mutilation," and with their loose statements unsupported by proved facts. Dr. E. Sutherland Rawlings has very ably refuted most of the statements which have appeared concerning the undesirability of circumcision during the past month. A few points remain to be cleared up. In over 50 per cent. of cases the prepuce simply cannot be retracted. Repeated interference with a child's genital organs, such as stretching, be it by mother, nurse, or doctor, is very strongly to be deprecated as a potent cause of masturbation. The fact that we *do not* operate on the clitoris is not synonymous with *should not*. Phimosis undoubtedly does occur in a small proportion of females. The lips or labia oris are covered with mucous membrane, and apparently get on quite well without protection—all the more reason why the glans should manage without it. Yes, convulsions and enuresis are less common in Jewish communities. It was never suggested that phimosis is the cause of all cases of enuresis. The family statistics offered are really rather limited; not only so, but the deductions accompanying them are wholly contradictory. The prepuce has no nerves of special sense, the bulb and glans only being supplied with Krause's end-bulbs.

Rheumatoid Arthritis

Dr. C. H. Foley (Athenry, co. Galway) writes: For some time my treatment of chronic rheumatoid arthritis has been limited to the injection, every seven days, of an ampoule of camphor in oil (1 c.cm.—3 grains), using a long serum needle, where necessary, to get as close as possible (as in the hip) to the external joint ligaments on the flexure side of the joint. The invariable result is comparative freedom from symptoms for a period of about one week to a fortnight in many cases. During these intervals the patient finds courage to move the joint. Cardiac conditions or cardio-vascular disease do not contraindicate this treatment; these cases actually improve under it. I commend this treatment to general practitioners who have felt, no doubt, as often I have felt, a positive repugnance to visiting the rheumatoid patient, finding, when we do, he or she has received no benefit from any of the immense list of drugs or treatment recommended. I have also occasionally given the injection this way. To 5 c.cm. of boiled milk I add one ampoule of camphor in oil, shake up well in the syringe barrel, and slowly inject. This is to obtain a wider dissemination of the camphor, but I have found no actual difference in the result, except a lengthening of the freedom interval.

Mammary Tuberculosis

Dr. Charles Wilcocks (medical officer in charge, Tuberculosis Investigation, Tanganyika Territory) writes: With reference to a recent letter from Dr. G. Jessel on the subject of tuberculosis of the female breast, the following case may be of interest. On June 6th, 1931, I saw a native woman here, aged about 50, with an enormously swollen left breast, freely movable over the ribs, containing large palpable nodules of different sizes, and a fluid swelling on the outer side. In the lower outer quadrant there was a sinus discharging thin pus. No swelling of the axillary or other lymph glands could be detected, nor were there any signs in the chest or ribs. A definite history of at least one year was given by a European who knew the woman. Material was withdrawn from one of the nodules by aspiration with a 5 c.cm. syringe, though there was no actual cascation clinically, and this proved to contain acid-fast rods morphologically identical with tubercle bacilli. No such bacilli could be found in the serous fluid withdrawn from the fluid swelling, which may have been cystic rather than inflammatory. The patient would not, unfortunately, consent to removal of the breast, but even without section I think the diagnosis may be regarded as proved.

Driving in Fog

At the recent International Illumination Congress the fallacy of using a yellow light to improve penetration during fog was effectively exposed by the representative of the Automobile Association. Fog contains minute droplets of water, which act as lenses, and, therefore, the more powerful the illumination, the greater is the reflection. Coloured glass merely reduces the intensity of the light. The following recommendations are made by the Automobile Association to assist motorists driving in fog: Direct a fairly intense concentrated beam to the near side of the road, either from a fog lamp on the near side dumbiron, or a spot-light attached to the near side pillar of the windscreen. Thus the driver is able to look either over or under the beam. Where special fog-directing lights are not available, extinguish the off-side headlamp and direct the other headlamp beam on the near side of the road. This method necessitates driving close to the near-side kerb. Again, tissue paper of one or more thicknesses attached to the outside of the headlamp glasses, or whitening mixed with water, will be found helpful. If the driver has a preference for any colour which suits his sight, tinted tissue paper, or dry colour mixed with the whitening will produce the desired effect.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 50, 51, 54, and 55 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52 and 53.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 287.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

Dermato-myositis

470 G. MARINESCO, S. DRAGANESCO, and E. FAÇON (*Ann. de Méd.*, July, 1931, p. 145) discuss, especially from its anatomical and pathological aspects, a case of dermato-myositis, a muscular affection first described by Wagner in 1863. The essential characteristics of this disease, which were evidenced in the present case, are fever with muscular troubles (atrophies and pareses), cutaneous signs, changes in the osteo-tendinous reflexes and muscle electrical reactions, and, histologically, infiltrative and degenerative lesions of the muscles with inflammatory processes in the skin. Among the muscles with inflammatory marked interstitial and parenchymatous changes were those of the abdominal wall, the crural triceps, and the brachial biceps. Examination of the nerves showed the presence of degenerative changes due to inflammatory lesions. Marked inflammatory processes were also found in the derma, and especially in the connective tissue of the skin. The differential diagnosis of dermato-myositis is briefly outlined. Various micro-organisms have been suspected as infective causes, and the authors advance the hypothesis of an ultra-virus as being concerned. Though absent in sections of the skin and muscles in the present case, streptococci were isolated from the tonsil. It is suggested that the tonsillar lesions caused by these allowed access of the ultra-virus into the organism. Goodpasture has noted that bacteria may act as carriers of neurotropic viruses, and the same hypothesis has been advanced concerning scarlet fever. Probably, previous diseases such as rheumatism and tuberculosis are predisposing etiological factors.

Tuberculosis Simulating Acute Leukaemia

471 E. R. MARZULLO and J. A. DEVEER (*Amer. Journ. Med. Sci.*, September, 1931, p. 372) consider that the haemopoietic tissues may occasionally respond to any infection in such a way as to produce a leukaemic blood picture, and that tuberculosis affords an illustration of such an infection. Two cases of tuberculous infection, one pulmonary, the other generalized, which presented myelo-leukaemoid blood findings and a clinical course simulating acute myeloid leukaemia, are reported. The presence of tuberculosis was the outstanding post-mortem finding, and tubercle bacilli were detected in the tissues. Characteristic leukaemic infiltrations in the tissues were absent, and the spleen and bone marrow showed only a moderate myeloid hyperplasia. Despite the blood findings, the usual haemorrhagic manifestations of leukaemia were absent before death, and both patients showed the physical signs of pulmonary tuberculosis.

The Mechanism of Alternation of the Pulse

472 N. KISTHINIOS and D. M. GOMEZ (*Arch. des Mal. du Cœur*, July, 1931, p. 410) consider that neither the theory of Wenckebach nor that of Gaskell and Hering is adequate to explain the production of alternation of the pulse. Their hypothesis, which in a measure embodies those quoted, is based on the fluctuating energy requirement of the isometric phase of ventricular contraction when exhaustion of the myocardium is accompanied by a high peripheral resistance. The high diastolic pressure in the aorta must be overcome by so large an output of energy that the heart is thereafter not able to empty itself adequately. Thus arises the small pulsation in the periphery. Since less blood has been put into the arteries, the diastolic pressure is not now so high, with the result that at the following contraction less energy is expended in the isometric phase, more being subsequently available for the production of a larger pulse wave. Hence the alternation of small and large pulsations. The authors cite animal experimentation to show that myocardial exhaustion and high peripheral resistance are important factors in the production of alternation. Clinical evidence in support of their view is found in the frequency of alternation in hyperpietics, and it is held that excessive exhaustion may account for the occurrence of alternation in some patients whose diastolic pressures are not much elevated. The clinical fact that the diastolic arterial tension falls after the weak and rises after the strong pulsation is also in support of their theory. The objection that alternation is not necessarily present when myocardial exhaustion and high peripheral resistance co-exist is met by the argument that the myocardium must be capable at least of a certain minimal energy output for alternation to appear.

Diphtheral Blepharitis

473 FRIEDMANN (*Deut. med. Woch.*, September 4th, 1931, p. 1542), who records two illustrative cases, remarks that diphtheria of the skin, which is generally regarded as a rare affection, occurs more frequently than is supposed. Cases presenting the appearance of a harmless eczema without any membrane may be encountered, and may prove refractory to all treatment until a bacteriological examination reveals the presence of diphtheria bacilli; rapid recovery follows the injection of antitoxin. Friedmann reports two cases of blepharitis; one in a child of 21 years, and the other in a servant girl, in whom the condition had been regarded as due to scrofula, and which had lasted two months in the former case and one year in the latter. Diphtheria bacilli were found on examination. The blepharitis cleared up in eight days in the case of the child, and in a fortnight in that of the servant.

Surgery

Aspiration of Joint Effusions

474 D. H. KLING (*Ann. of Surg.*, September, 1931, p. 3[illegible] emphasizes the importance of aspiration of joint fluid in both of traumatic and of inflammatory origin, and gives the following reasons for this procedure. The accumulation of fluid expands the capsule, stretches the ligaments of the joint, interferes with the circulation, and irritates the nerve apparatus, causing spasm of the muscles. The blood, being absorbed slowly from the joint, produces inflammatory changes of the synovial membrane. Fibrin is also precipitated and organized, and may form a nucleus for the development of loose bodies. The cartilages undergo degeneration, and the immobilization of the joints may give rise to atrophy of the muscles and bone. Aspiration under aseptic conditions is harmless, no cases of infection having been reported, and a repeated aspiration is necessary in only a few cases. Aspiration should be carried out twenty-four hours after injury in cases of traumatic effusion, the fluid being examined to determine the severity and type of the injury. Cases of simple traumatic synovitis are mobilized immediately, and walking is permitted after a few days. In 160 cases of injury with haemarthrosis complete recovery ensued within ten days. Injuries to the cartilages, and inter-articular fractures, need further surgical treatment after the evacuation of the effusion. The examination of the traumatic effusions permits the differentiation of slight from severe injuries and intra-articular fractures by the finding of fat and bone-marrow elements. An objective differential diagnosis between inflammatory and traumatic effusions is made possible by the estimation of the uterus index or van den Bergh reaction of the synovial fluid. The *p*H estimation is of some value for prognosis in cases of purulent arthritis, severe cases give an acid reaction.

475 Latent Haemorrhage in the Thyroid Gland

P. Bertrand and F. Carcassonne (*Lyon Chirurgical*, September–October, 1931, p. 548) point out that, of the various complications of goitre, latent haemorrhage has received insufficient attention; they record particulars of twenty such cases which were found in a series of seventy operations for non-cancerous goitre. The majority of these cases are found in patients between the ages of 40 and 50, frequently about the time of the menopause in women. Of the twenty cases quoted only one occurred in a man. This condition is generally attributed to the extreme fragility of the capillaries of the thyroid tumour; they have very thin walls, and form a rich capillary network. Moreover, the difference in tension at menstruation between the contents of these capillaries and of the goitre, accounts for the escape of a considerable quantity of blood into the interior of the hypertrophied thyroid gland. There are three different varieties of latent haemorrhage, the first of which occurs in a cystic goitre, when the blood found is more or less modified, being sometimes fluid and sometimes in the form of clots. Another form appears in a parenchymatous goitre, and is often a precursor of malignant changes. The third variety is interstitial and less abundant, being rarely verified until some time after its production. The most common symptom is an increase in the size of the goitre, noticed either during pregnancy or after the menopause, but a correct diagnosis is rarely made except at operation. In other cases the symptoms are very similar to those found in malignant degeneration of the thyroid, with increase in size, dyspnoea, and hoarseness of voice; the operation is usually undertaken on a diagnosis of malignant disease. It is in cases of this nature that operation alone is able to verify the true nature of the condition, and relieve the patient. In the twenty cases under review, removal of the goitre was effected with good results. There was only one death; the remaining patients made a good recovery and left the hospital completely cured.

476 Reflex Tenderness in Gall-bladder Disease

G. Levene (*New Eng. Journ. Med.*, August 20th, 1931, p. 403) calls attention to the reflex tenderness which is evoked by slight pressure over the right costo-vertebral angle as being a consistently more reliable sign of gall-bladder disease than anterior subcostal tenderness. Though previously described by Boas in 1895 as being diagnostic of cholelithiasis, lesser degrees of gall-bladder disease can be detected thereby. With the patient lying prone, and the arms by the sides, the examiner places the middle finger and thumb over the costo-vertebral angles; he makes gentle pressure first on the left side and then on the right, afterwards exploring the area from the tenth to the twelfth ribs in a zone one or two inches from the spine. The left side should be palpated first in order to ascertain the patient's general reaction. Any tenderness due to gall-bladder disease is invariably higher than that produced by disease of the right kidney, but its location may vary by as much as one or two ribs, according to the position of the gall-bladder. In an analysis of 100 unselected cases the sign was present in 92.3 per cent. of patients with definite evidence of gall-bladder disease; it was absent in 95.7 per cent. of normal cases. Of thirteen cases operated upon, in whom the diagnosis was confirmed histologically, the sign was present in 92.3 per cent.

477 Lumbo-sacral Spina Bifida Occulta

Emphasizing the clinical importance of spina bifida occulta, R. J. Dittrich (*Surg., Gynecol. and Obstet.*, September, 1931, p. 378) records a study of this condition with short notes on three cases. The disease is a congenital defect, found usually in the lumbo-sacral region, and frequently associated with other abnormalities which cause the symptoms. The abnormalities generally consist of masses of fibrous and muscle tissues and fat, which are found in or near the bony defect, and by extension interfere with the function of the nervous structures underneath the cleft. Developmentally, the most probable process of malformation is one which affects the bony structures, the alteration in the soft tissues being caused by transposition. Such a mechanism of formation is most nearly in agreement with the pathological changes seen at necropsy and at operation, and must be distinguished from the process of primary malformation in the cord itself. Clinical observations indicate that a large number of syndromes can be definitely traced to such anomalies of the spine. The importance of spinal clefts is illustrated by the investigations of Lampar, who found among forty cases of spina bifida occulta only one which did not present neurological symptoms. Treatment must depend largely on the gravity of the symptoms. Laminectomy and the removal of injurious influences have yielded a relatively high percentage of beneficial results.

Therapeutics

478 Specific Prophylaxis of Meningitis

J. A. Kolmer and K. W. Amano (*Arch. of Oto-Laryngol.*, August, 1931, p. 125) point out that the present methods of treatment of pneumococcal and streptococcal meningitis are so unsatisfactory that the mortality rate is excessively high; they have endeavoured to devise methods of specific prophylaxis by means of serums for these infections. Experiments on monkeys, dogs, and rabbits indicated that it might be possible to prevent post-operative pneumococcal meningitis by the administration of anti-pneumococcal serum with or without ethyl-hydrocupreine hydrochloride. The outlook in streptococcal infections is not so good, but the following technique is advised in cases of these infections. Bacteriological examinations should be made of the pus from infected sinuses before they are opened up, and of mastoid pus at the operation. In adult infections with Type I pneumococcus, 10 c.cm. of Felton's concentrated anti-pneumococcal serum should be injected just before or immediately after the operation. A second dose should be given on the following day, and a third one four days later. In Type II and IV infections, the same dosage, or 15 c.cm., should be used, and in Type III cases 20 c.cm. The same doses should be given to children over 10 years of age; half-doses to younger children. Ethyl-hydrocupreine hydro-chloride in 5-grain doses should be administered with milk every five hours for three days after the operation; children require less, according to weight. In streptococcal infections a scarlet fever antitoxin, or a concentrated polyvalent anti-streptococcal serum, should be injected in the doses here prescribed.

479 Immuno-transfusion in Streptococcal Septicaemia

P. Abrami and A. Tzanck (*Paris Méd.*, August 1st, 1931, p. 104) report on the treatment of 43 cases of severe streptococcal septicaemia, of which 22 were cured. Of 21 patients who gave positive blood cultures, 12 were cured and 9 died, among whom 3 treated by immuno-transfusion showed marked improvement though death supervened from broncho-pneumonia (2 cases) and peritonitis (1 case). In the 19 cases in which the blood cultures were negative, 9 patients were cured and 10 died; 4 of the latter showed marked improvement after blood transfusion, death being delayed, and due to local complications. Owing to the varying type of case and the employment of different therapeutic measures—immuno-transfusion, simple transfusion of blood, and no transfusion—it was not possible to attribute the results to any particular vaccine method, since very favourable results followed independently of any such treatment, and simple blood transfusion gave results similar to those obtained by immuno-transfusion. Since the object of immuno-transfusion is to confer on the patient the benefit of an artificial immunity, it is first desirable to show whether in the healthy donor there is evidence of the production of immunity by vaccine injections, and secondly, whether the transfused blood is the true cause of the favourable symptoms which ensue in the patient. The indication for true immuno-transfusion is found in those diseases capable of producing immunity.

Independently of any specific immunity activity, a blood transfusion carries a number of non-specific properties which can help the cure of the disease without any question of immunity production; to these properties the authors have given the name of "biophylaxie."

480 Artificial and Natural Heliotherapy

As the result of a detailed study of heliotherapy in the treatment of tuberculosis, E. S. MARIETTE (*Minnesota Med.*, September, 1931, p. 793) concludes that light therapy is a potent agent which, unless carefully supervised, will do great harm; where a general radiation of the whole body is indicated, the best results will be obtained from natural sunlight. However, indications for artificial or natural light will depend on the season, the condition of the atmosphere, the sources of light available, the type of lesion to be treated, and the patient's condition, these points are fully discussed. Various sources of artificial light are enumerated; since the spectrum of the carbon arc lamp with the core-D filter and the white flame carbon most closely resembles that of natural sunlight, it is concluded that it supplies the artificial light of choice. Cases of tuberculosis for heliotherapy are divided into two groups, the extrapulmonary and the pulmonary, and these again are subdivided into five classes. Classes 1 and 2 include extrapulmonary forms, the former without, the latter with pulmonary complications. Class 3 comprises juvenile cases, Class 4 includes the "productive," proliferative, or fibroid cases, and Class 5 is made up of exudative cases in adults. Heliotherapy is indicated in all cases of the first three classes, but only in selected cases that do not improve under sanatorium treatment in Class 4; it is contraindicated in all cases of Class 5. The technique of the sun bath and the dosage of light are described.

Neurology and Psychology

481 Lesions of the Sympathetic Centres of the Diencephalon

According to G. GUILLAIN, R. GARCIN, and J. MOGE (*C. R. Soc. de Biologie*, July 21st, 1931, p. 1274), topographical knowledge of the sympathetic centres in the upper neuraxis is still vague and fragmentary, they consider that the simultaneous appearance (as the result of thalamic softening) of a hemialgic syndrome of one side and a syndrome of Claude Bernard-Horner (enophthalmia, narrowing of the palpebral fissure, and myosis) of the other side is noteworthy. Such a case is recorded in which the essential symptoms were hemialgic sensory troubles of the right side without pyramidal signs, and a typical Claude Bernard-Horner syndrome of the left. Both appeared concurrently, following probable cerebral softening in the left thalamic region. The pupillary reflexes were normal, and ocular paralysis was absent. The limbs of the right side showed marked cyanosis with oedema of the calf and a slightly increased cutaneous temperature. The left side was normal. Thus the patient had a right vaso-paralysis with a left oculo-sympathetic paralysis; that is, a true alternate syndrome of sympathetic paralysis. The work of other investigators, here cited, proves that the symptoms in the present case were not merely coincidental.

482 Cerebral Development and Behaviour

F. TILNEY and L. S. KUBIE (*Bull. Neurol. Inst. of New York*, June, 1931, p. 229) report investigations designed to establish, if possible, a basis for defining behaviour in terms of cerebral structure. The structural side of the research comprised organogenetic studies by means of the Born method of reconstruction, together with histogenetic and myelinogenetic studies. A review of the developmental processes in the endbrain of the cat suggests that this structure passes successively through the stages which recapitulate ichthyopsid and reptilian conditions before the ultimate mammalian cortex is attained. The earliest tract-beds to appear are the lateral olfactory and thalamo-cortical. The optic tract-bed, although recognizable at an early period, maintains for a long time its ancient relations with the midbrain and interbrain, and is independent of the endbrain, to which it extends relatively late in development. The authors conclude that the functional evolution of that part of the brain which represents the highest specialization in behaviour depends in the cat primarily on the projection of the senses upon specialized cortical areas, in which process a general body sense precedes the special senses. It depends, secondly, on the bilateral association of these senses in the two hemispheres, in this again the general body sense takes precedence over the special senses. This feature of development involves all the important considerations of right or left cerebral dominance. Thirdly, this functional evolution is based on intimate associations and elaborations within each type of sense as well as interassociations between all the senses. The efferent projection of sensory associations into the somatic activities is the fourth fundamental of the animal's behaviour. The authors add that this formula for the functional evolution in the last developed part of the cortex applies probably, as a general rule, to all mammals, with certain modifications for different species.

483 Psychotic Manifestations in Thyroidism

In view of the problematical relationship of thyrotoxicosis to the psychoses, S. D. INGHAM and J. M. NIELSEN (*Journ. of Nerv. and Ment. Dis.*, September, 1931, p. 271) discuss the diagnostic difficulties in psychosis of thyroid origin, and report four cases with a view to showing that toxic thyroidism may be the primary cause of an associated psychosis. They point out that estimation of the basal metabolic rate is an unreliable way of determining the presence or absence of a toxic thyroid condition and add that the type of psychosis may vary markedly in different cases, and even in the same case from time to time. If there are no physical contraindications surgical treatment may be undertaken, regardless of the presence of psychosis. In their four cases the usual treatment for the manifest psychosis was tried in vain, but recovery promptly ensued when specific thyroid therapy was instituted. In cases of thyrogenous psychosis there may be a normal metabolic rate, this has to be borne in mind when attempting to reach a diagnosis. Psychosis of essential thyroid origin may simulate either of the two phases of manic-depressive psychosis, it may also resemble dementia praecox, delirium, or any toxic psychosis. Even in an undoubted case the clinical signs of loss of weight, fatigue, eye changes, and thyroid enlargement may be entirely absent. The authors urge extreme caution in ascribing any psychosis to psychogenic factors without a most thorough search for some toxaemic source. They doubt whether a frank psychosis ever occurs without at least a chemical disturbance of the cerebral function.

Obstetrics and Gynaecology

484 Radium Treatment of Menorrhagia

Control by radium of excessive menstrual and intermenstrual bleeding, especially in cases where the only alternative is subtotal hysterectomy, is now recognized as the treatment of election. C. C. ANDERSON (*New Zealand Med. Journ.*, August, 1931, p. 202) records a case to illustrate the fact that pregnancy may occur after this procedure, but that complications may ensue. A woman became pregnant about three years subsequent to beneficial radium treatment for severe menorrhagia. At labour a firm, almost cartilaginous, undilatable band was found at the internal os. The foetus was dead and Cæsarean section was performed. The patient is now well and without pelvic trouble, but has not menstruated since the operation. This case illustrates that, in women within the child bearing period, excessive menstruation can be controlled and normal menstruation restored, and that

the endometrium, despite the changes induced by radium, can still provide a nidus for the normal development of the ovum. Changes may, however, be produced in the uterine muscle which may prevent completion of the normal period of gestation, and an intense cervical fibrosis may prohibit the necessary dilatation. Anderson emphasizes the point that radium treatment should only be undertaken after other measures have been tried and have failed, and the only remaining therapeutic possibility is hysterectomy.

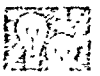
485 Perforating Chorion-Epithelioma of the Uterus

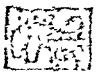
Chorion-epithelioma is due to the continuous and abnormal proliferation of the chorion epithelium, and consists of masses of syncytial and Langhans's cells interspersed with remnants of the invaded tissues and blood from the corroded vessels. B. M. Anspach and J. Hoffman (*Amer. Journ. Obstet. and Gynecol.*, August, 1931, p. 239) record a personal case, and comment on six others culled from the literature relating to a perforating type of these tumours in which the growth had penetrated through the serous uterine coat into the peritoneal cavity, causing free, unlimited, and grave intraperitoneal haemorrhage. The clinical course of most of these cases so closely resembled a ruptured ectopic gestation that the latter diagnosis was made in five instances. A distinct, differential symptom is the absence of profuse external haemorrhage, since the tumours are often situated within the uterine wall, and do not communicate with the uterine cavity. The immediate cause of perforation may be some form of traumatism, such as a vigorous bimanual examination; therefore, such examinations should be made with care in suspected cases. The diagnosis cannot be determined decisively until the parts are exposed; the perforation is at the site of a localized enlargement of the uterus. In these cases the uterus, with the adnexa, must be removed well below the growth, and subsequent irradiation be applied. The acute, profound anaemia prohibits a complete hysterectomy. In two cases symptoms of cerebral involvement occurred, and in another instance haemoptysis was a precursor of perforation. As the urine of women with chorion-epithelioma or hydatid mole gives a pregnancy reaction twelve times as strong as a two months gestation, the Aschheim-Zondek test is of value, and should be performed in all suspicious cases.

486 Diabetes Mellitus and Pregnancy

C. H. Peckham (*Bull. Johns Hopkins Hosp.*, September, 1931, p. 184) presents a study of eighteen pregnancies in twelve diabetic patients. Insulin has rendered the prognosis much more favourable. The general opinion is that the mild or moderately severe case, under supervision, will pass through pregnancy and labour fairly safely, but in severe cases induction of labour may be necessary, for ketonuria occurs more readily. Several cases of diabetic coma are reported, some being fatal. Insulin requirement decreases usually during the puerperium, but increases subsequently. The percentages of abortions and stillbirths remain high, but infantile nutrition is good. Many diabetic women conceive after insulin treatment. Ten of Peckham's twelve patients have survived; in four the diabetes probably developed during pregnancy, but the other eight had been known diabetics for from one to fifteen years, the average duration being approximately six years. One was diabetic in 1919; she passed through two pregnancies and died from pneumonia in 1929, three years after her last confinement. The other fatal case was that of a woman admitted for the first time when eight months pregnant, and having been comatose for two days. In spite of the administration of insulin and fluids she died in a few hours. This is the only death of an actually pregnant patient in the series. The author concludes that pregnancy causes little if any disturbance of the carbohydrate metabolism, although in ten cases the diabetes was aggravated during the first four months; the considerable glycosuria necessitated increased insulin dosage and stricter dieting. As term approached, these patients improved greatly. One secundipara required an insulin increase of 20 to 40 units, but at the eighth month, 20 units daily sufficed, and the urine was sugar-free. Nephritis necessitated the induction of labour three weeks before term. The mother suckled the child for one month, and lactation appears to be beneficial. Acidosis occurred occasionally, but was controlled by an increase in the carbohydrate intake.

Pathology





487 Histological Changes in the Diseased Thyroid

W. F. Rienhoff, jun. (*Medicine*, September, 1931, p. 257) discusses the pathogenesis of some morbid changes encountered in diseases of the thyroid, basing his observations on experimental studies of the normal gland, and of the alterations it undergoes in exophthalmic goitre. The characteristic enlargement in this disease, both in the follicles and in the gland, which is concomitant with hypertrophy and hyperplasia and in the involution, is due in the active phase to an increase in the parenchyma, and in the inactive stage of involution to the deposition of colloid. This enlargement may occur in localized regions, or throughout the whole gland, and must be distinguished from actual structural growth as observed in neoplasms. By the interaction of the two processes (hypertrophy and hyperplasia with involution), a normal gland may be transformed into a nodular goitre following a localized or diffuse involvement of the gland in the morbid process. If involution occurs in a normal gland, not preceded by hypertrophy and hyperplasia, there has been a uniform increase in the size of the follicles with a flattening of the epithelial cells, and an increase in the follicular colloid. This process may also be localized or diffuse. If diffuse, a condition similar to simple colloid goitre is produced, whereas areas indistinguishable from colloid adenomata will evolve from regional involution of a normal gland in which only certain areas are invaded by the regressive process. The fundamental causes of hypertrophy and hyperplasia and of involution are yet unknown, hence many alterations in the structure and function of the thyroid remain unexplained.

488 Effect of Diuretics on the Excretion of Sugar

H. Bix and L. Wechsler (*Wien. Arch. f. Innere Med.*, July 15th, 1931, p. 427) state that in most cases of diabetes mellitus an increase in the amount of urine passed is associated with an increase in the amount of sugar excreted. Several diabetic patients, whose glycosuria on insulin and a standard diet was practically constant, were given injections of a powerful diuretic, salyrgan, in order to ascertain whether the increased output of urine "washed out" additional sugar from the tissues. It was found, however, that in all but 5 per cent. of the cases the total amount of sugar excreted was diminished as long as the diuresis lasted, and only returned to its original value when the diuresis subsided. This was frequently followed by a rise in sugar excretion one or two days later. In order to ascertain how salyrgan produced this diminution in glycosuria the blood sugar curves with and without salyrgan were compared. It was found that within an hour of the administration of salyrgan the blood sugar began to rise, reaching a maximum in three hours and falling to its original fasting level at the end of twenty-four hours, while without salyrgan the blood sugar remained fairly constant throughout the twenty-four hours. Salyrgan thus apparently raises the renal threshold for sugar, and produces a retention of sugar in diabetics. It is therefore generally inadvisable to administer the drug to diabetics, though apparently in a few cases increased sugar tolerance followed injections of salyrgan in patients on insulin. In a number of animals in which renal glycosuria had been induced by phloridzin the glycosuria was similarly diminished, thus confirming the hypothesis that the glycosuria-inhibiting action of salyrgan takes place in men and animals in the kidneys.

WE MODERNS PREFER

electric lights  to old oil lamps  and motor cars  to the horse and gig  of an earlier age  because we get results more quickly and more efficiently.

Similarly in constipation — a modern day has developed a modern way — AGAROL. To meet every modern need, this product combines efficiency with palatability. No oily taste, no artificial flavouring to get used to.

AGAROL Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

Effectiveness must be experienced.
A supply gladly sent for trial.

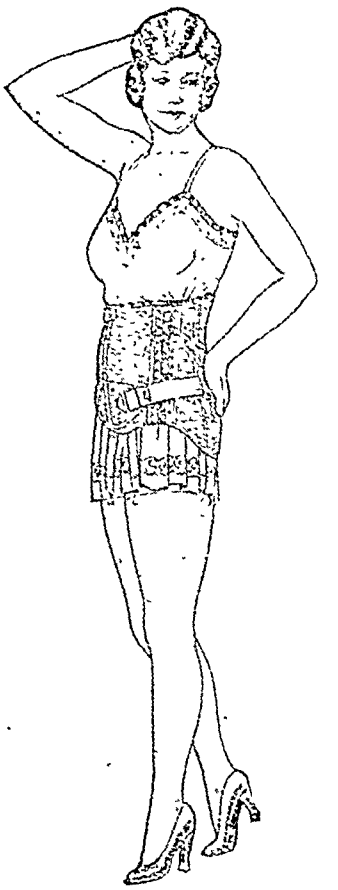
Salt and Son Ltd.



SALT'S MATERNITY BELT CORSET.

From our own experience, and confirmed by the opinion of many Medical Men, we are convinced that this Corset is vastly superior to anything previously made.

This opinion is based on the following reasons:—

1. It has an elastic front with lacing at each side, which allows the necessary expansion.
2. It has a deep back, closed and firmly boned, which gives maximum support.
3. It is not carried above the waist in front, thus avoiding pressure on Bust.
4. It has a lower abdominal support, which provides maximum uplift.
5. It gives great comfort to the wearer by reason of its simplicity and elasticity.
6. It is ANATOMICALLY CORRECT throughout.

London Consulting Rooms:
"OAKLEY HOUSE,"
14-18, Bloomsbury St., W.C.1
Female Fitters in attendance Monday to Friday.
Orthopaedic Mechanician Wednesdays only.
By Appointment.

As in the case with all Salt's Special Appliances, this Corset is supplied in varying qualities, to suit the means of all, and is made ONLY to the requirements of each individual case.

Works Tottenham

Telegrams Instruments, Wesdo London

DEAF DOCTORS
AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: *"'Ardente' is a godsend to me"*; without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what 'ARDENTE' service stands for to the deaf. Many doctors who are deaf use "ARDENTE"

"ARDENTE" is entirely different and uncopyable and succeeds in widely differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young, middle aged, or old, and so sensitive as to have the desired effect even in middle ear and nerve cases, bringing into action and stimulating the auditory system, enabling it to function naturally and saving atrophy. "ARDENTE" can be used or not at will, and is sold under guarantee.

"ARDENTE" is the choice of Doctor and patient—only after test and hearing or from prescription or particulars, is "ARDENTE" fitted, toned, tried, adjusted, supplied, and serviced.

Tests and demonstrations given at Doctors', patients' or our addresses, without fee or obligation.

An IMPROVED and MODIFIED
Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions

Extension of whole lower limbs
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation
Flexion of knee-joint.
Inversion and Eversion of foot

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35in × 15in × 11in.

AN INTELLIGENT PATIENT given diagnosis and instruction is cured on request. Please ask for it.

To those whose need of the best woollen underwear is imperative, the wisest word to say is Wolsey. For Wolsey underwear is soft and warm and comfortable. Scientific investigations* have proved that garments made of wool do more than any other to prevent the deposition of moisture on the skin; retain warmth better than any other material, and allow the most equable body temperature possible. And the purity and goodness of the wool from which Wolsey is made give it all these qualities which are essential to health and wellbeing.

* By the British Research Association for the Woollen and Worsted Industries, detailed reports of which will be sent free on application to Wolsey Ltd., Leicester.

THE EXPERIMENTAL STUDY OF READING

By M. D. VERNON

Large crown 8vo. *With* 15 *Illustrations.* 8s. 6d. net.

The purpose of this book is to give a concise account of any experimental work, particularly that recently performed, which throws some light on the psychology of reading.

The acquirement in reading of a specially adapted series of eye movements is fully described. The reading perceptions of adults, and their relation to perception in general, are outlined, together with the development and disabilities of reading perception in children. Finally some account is given of the effect upon reading of variations in the printed text.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

Extract from the "British Medical Journal," Dec. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . Madame Rose has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary *patients* and certified patients of both sexes are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a *Reception Hospital* in detached grounds with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 *acres*. *Milk, meat, fruit* and vegetables are supplied to the Hospital from the farm, gardens and *orchards of Moulton Park*. Occupation therapy is a feature of this branch and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 350 acres at Llanfairfechan, amidst the finest scenery in North Wales. On the North West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for hand-raft such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 50 Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

HAYDOCK LODGE,

NEWTON-LE-WILLOWS, LANCASHIRE.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULLS, M.R.C.S., L.R.C.P.
Telephone: Teignmouth 289.

RUTHIN CASTLE, NORTH WALES

REDUCTION OF FEES

In view of the present economic position, the inclusive fees at Ruthin Castle, formerly from 17 guineas a week, have been reduced to from 15 guineas a week, beginning on October 19th, 1931.

The fees include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary x-ray examinations, and electrocardiograph readings, all treatment that may be prescribed, such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, nursing, medicines or vaccines, board and lodging.

The only extra charge is that for a complete alimentary x-ray examination, or for x-ray therapy.

Many people who would go abroad for health will not do so this winter. All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 29·5 inches, that is, less than the average for England. There is central heating throughout. Should the accommodation in the Castle not prove sufficient, comfortable rooms can be obtained near by for those undergoing treatment.

Address—THE SECRETARY, Ruthin Castle, North Wales. *Telegrams*: CASTLE, RUTHIN. *Telephone*: RUTHIN 66.

North Staffordshire Royal INFIRMARY, STOKE-ON-TRENT.

(A General Hospital with 350 Beds.)

ORTHOPAEDIC SURGEON.

The General Committee invite applications for the appointment of Orthopaedic Surgeon to this Infirmary, the Orthopaedic Department of which is being reorganised. Applicants must possess the degree of Master in Surgery (obtained by Special Examination) of a British or Irish University, or the degree of Master in Surgery (Orthopaedic) of Liverpool University, or the diploma of Fellow of one of the Royal Colleges of Surgeons of Great Britain or Ireland.

The Orthopaedic Surgeon must devote the whole of his time to the specialty.

He will be permitted to practise in the district—so long as he confines himself to the practice of Orthopaedic Surgery, and does not engage in General practice.

Until such time as he has been able to establish himself as a consulting Orthopaedic Surgeon, the salary will be at the rate of £500 per annum, non-resident.

The position will be reviewed by the Committee at the end of three years.

Applications, with copies of three testimonials, to be sent to the undersigned immediately.

Any further information may also be obtained on request.

By Order of the General Committee,
W. STEVENSON,
November 16th, 1931. Sec. & House Gov.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. Telephone: TEMPLE BAR 1616 (3 Lines).

Under the personal directorship of Dr. J. FIELD HALL and J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges. No charge is made to Principals for the introduction of Locum Tenens or Assistants.

1. SOUTH WALES.—Residential district, close to coast.—Old-established good middle-class PRACTICE, averaging over £2,000 p.a. Panel of 1,100. Fees 3/6 to 10/6. Mid. from 3 gns. House contains 3 reception, 5 bedrooms, etc. Can be rented or purchased. Sport of all kinds, and good schools. Premium 1½ years' purchase.

2. NORTH WALES.—Very old-established good mixed-class PRACTICE, averaging £880 p.a., including panel of 433. Fees 2/6 to 10/6, medicine extra. Suitable house, with 2 reception, 6 bedrooms, etc. Can be rented on lease at £50 p.a. Good sport. Premium £1,200, part down and balance by instalments. Ill health reason for sale.

3. WEST OF ENGLAND.—LARGE TOWN.—Well-established PRACTICE, producing nearly £900 p.a., including panel of over 1,300. Suitable house, in excellent position. Price £700, or can be rented at £60 p.a. Premium £1,450. Good scope for increase.

4. SOUTH-WEST OF ENGLAND.—FAVOURITE COAST TOWN.—Old-established good middle class non-dispensing PRACTICE, averaging £2,100 p.a. Selected panel of 700. Very good appointments worth about £400 p.a. Fees 5/- to 21/-. Midwifery from 5 gns. About 10 cases yearly. House contains 2 reception, 4 bedrooms, etc., waiting, and consulting rooms. Freehold can be bought, or other suitable houses available. Good hospital in the town, and excellent scope for surgery, particularly if successor holds a Fellowship. Premium 2 years' purchase.

5. ESSEX.—COAST TOWN.—Increasing PRACTICE, situated in good residential district, and producing over £1,000 p.a. including selected panel of 100, and good appts. worth about £210 p.a. Large modern house, with beautiful garden; can be rented or bought. Premium £1,150.

6. LONDON, S.W.—Good middle class PRACTICE, offering considerable scope, and producing for the past 12 months over £670, including panel of nearly 400. Fees from 2/6. Midwifery 3 gns. (about 30 cases yearly). Suitable house, with dining room, consulting room, and dispensary, 3 bedrooms, sitting room, etc. Price for leasehold (94 years to run) £1,200, part on mortgage. Premium £1,050.

7. MIDLANDS.—PARTNERSHIP.—A one-third share is offered in a very sound middle and working-class Practice, held by the senior partner for 35 years. Average gross cash receipts for the past three years nearly £3,000. Panel of over 1,600. Fees 3/6 to 21/-. Midwifery from 3 gns. (about 60 cases). Suitable house available on rental, with 2 reception, 3 bedrooms, etc. Small garden. Garage. Sport of all kinds, and very good schools within reach. Prem. 2 years' pur.

8. NORTH OF ENGLAND.—FAVOURITE COAST TOWN.—Old-established middle and upper class non-panel PRACTICE, averaging for the past three years nearly £5,000. Fees from 5/- to 21/-. Very suitable for two friends in partnership, one holding the F.R.C.S., as there is excellent surgical scope. Two good houses available, with ample accommodation, either on rental, or by purchase.

9. MID-WALES.—Agricultural District.—Mixed class PRACTICE, producing about £880 p.a., including small panel of 130. Fees 3/6 to 21/-. Small house, with 2 reception, 3 bedrooms, etc. Price £550. Fishing, shooting, and other sport. Premium 1 year's purchase.

10. WEST OF ENGLAND.—Old-established general PRACTICE, situated in exceptionally nice neighbourhood, with good sporting and social facilities. Income averages about £1,000 p.a., with small panel of 400. Fees from 3/6 to 1½ gns. Particularly good house, with beautiful garden, and containing 2 reception, 7 bedrooms, etc. Price for freehold £2,000, part on mortgage. Excellent surgical prospects. Premium 1½ years' purchase.

11. WOMAN DOCTOR'S PRACTICE.—YORKS.—LARGE TOWN.—Established eight years, easily worked, and producing nearly £700 p.a. Panel of 500. Fees 5/- to 7/6. Midwifery 3 to 5 gns. Compact house, with 2 sitting, 2 bedrooms, 4 attics, etc. Garden. Garage. Rent on lease £42 10s. p.a. Prem. 1½ years' purchase, or near offer.

12. SOUTH OF ENGLAND.—Favourite Coast Town.—NURSING HOME, with small private Practice combined, the latter offering very good scope for development. Total receipts last year about £600. Very nice detached house, with excellent accommodation, very well appointed. Price for leasehold (87 years to run) £2,100, or can be rented at £140 p.a. Premium for goodwill, to include handsome furniture, fittings, etc., £1,250.

13. MIDLANDS.—COUNTRY TOWN.—PARTNERSHIP.—A one-fourth share is offered in an exceptionally sound good mixed-class Practice, averaging over £6,000 p.a., including panel of 3400. Lowest fee 4/-. Very little midwifery. If single, purchaser can live in comfortable rooms, otherwise choice of houses for sale or on rental. Premium 2 years' purchase.

14. NORTH OF ENGLAND.—GOOD TOWN.—A one-third share is offered in a very sound Practice, averaging about £5,000 p.a. Ingoing Partner must be well qualified and not over 35, and interested in medicine. Suitable house available. Premium 2 years' purchase.

15. CHESHIRE.—NEAR COAST.—Old-established middle and working class PRACTICE, averaging for the past three years over £1,300. Panel of 550. Fees from 3/6. Good house, with 3 reception, 7 bed rooms, etc. Price for freehold £1,200, part on mortgage. Premium 2 years' purchase.

16. WITHIN TEN MILES OF LONDON. — PARTNERSHIP. — The third share of an old-established good middle and working class Practice is for disposal, offering excellent future prospects. Cash receipts last year amounted to nearly £2,700, including panel of nearly 1,500. Suitable house available at moderate price. Premium £1,800.

17. WITHIN FOUR MILES OF THE BANK.—Old established working-class PRACTICE, producing for the last 12 months £2,300, including panel of over 2,800. Appts. worth about £160. Visits from 2 d. Low expenses. Suitable house can be rented or bought. Surgery premises on rental. Premium £4,000 cash.

18. NORTH-WEST COAST.—SURGICAL PARTNERSHIP.—In a popular residential seaside resort the half share of middle and upper-class Practice is offered to a suitable gentleman possessing the F.R.C.S., as the retiring partner does the surgical work, the remaining partner the medical side. Receipts average nearly £5,000 p.a. Very good modern house, recently built, with ample accommodation, good garden, tennis court, etc. Rent on lease £240, or can be purchased. Premium 2 years' purchase.

19. SOUTH AFRICA.—Within 100 miles of East London.—Increasing PRACTICE, in very pretty Township near sea coast, producing last financial year £1,066. Practically all fees cash. Climate excellent. No night work and little or no visiting. Living cheap. Buraalow residence in 3/4 acre of productive garden. Premium for Practice and house £1,155. Sport of all kinds.

20. BORDERS OF BERKS AND HANTS.—In a delightful sporting agricultural district, within reach of market town, an old established mixed-class PRACTICE averaging about £850 p.a., including panel over 400. Visits 5/- to 10/6, medicine extra. House containing 2 sitting, 7 bedrooms, bathroom, etc. Large garden. Garage. Let £50 p.a. on lease. Premium £1,100.

21. DEVON.—PARTNERSHIP.—Half share of very old-established and well-disposed Country Practice, offering scope, and situated in pretty village within reach of large town. Cash receipts last year £2,2... including appts. and panel of 880. Visits 5/6 to 21/-, medicine extra. House contains 2 reception, 4 bedrooms, bathroom, etc. Large garden. Garage. Rent £30 p.a. Premium £2,000. Hunting, shooting, fishing, etc.

22. NORTH DEVON & CORNWALL BORDERS.—Very old established well-opposed Country PRACTICE, in beautiful district near coast. Cash receipts average just over £1,100 p.a., including appt. and panel of 330. Suitable house available. Premium £1,600, to include drugs, etc. Hunting, golf, fishing, etc.

23. SOUTH OF ENGLAND.—Pleasant Town near Coast.—Very old established middle and upper-class PRACTICE. Cash receipts average nearly £1,750 p.a., including panel of 500. Visits 5/6 to 21/-. Very little midwifery. House, including consulting room, waiting room, and dispensary, in well-situated part of town. Price, freehold, £1,500.

24. CATHEDRAL CITY (NORTH).—PARTNERSHIP.—Third Partner required in very old-established lucrative and increasing middle and working class Practice. Cash receipts for past three years average £4,544 p.a. (last year £4,911), including panel about 4,000. A fifth share is for disposal, with increase to a third later. Suitable accommodation available. Premium 2 years' purchase.

25. NORTH MIDLANDS.—WITHIN 3 MILES OF FAVOURITE TOWN.—Old established good middle class PRACTICE, offering large scope. Cash receipts for last 12 months £1,332, including panel of over 1,000. Fees from 3/6. Mid. from 2 gns. Exceptionally nice house in about 4 acres of ground, with tennis lawn, fruit and vegetable gardens, etc., containing 3 reception, 6 bedrooms, etc. Freehold for sale. Premium 1½ years' purchase.

26. MANCHESTER.—Semi-residential Suburb.—Very old established non-dispensing mainly middle-class PRACTICE, averaging £2,500 p.a., including small selected panel of 440, which latter is capable of extension. Visits 5/- upwards. Only about 20 cases of Midwifery from 5 gns. Well situated house, with good accommodation. Price (freehold) £1,600. Premium £3,750.

27. LINCS. — PLEASANT MARKET TOWN. — PARTNERSHIP. — A half share, with possible succession in two years' time. Average income for past three years £1,900, including appointments and panel producing £500. Advice and medicine 5/- upwards; visits from 5/-. Very few midwiferies from 2 to 3 guineas. Large house with garden and garage. Price freehold only £1,200. Sport of all kinds, and excellent schools for boys and girls. Premium 2 years' purchase, payable £1,000 down, remainder by arrangement.

28. LANCS.—LARGE TOWN.—Old-established better end mid-class PRACTICE, producing last year over £1,400. Including panel of 970. Visits 2/6 to 10/6, with medicine extra. Suitable house, with 2 reception, 6 bedrooms, etc. Garage, garden. Rent on lease £90 p.a. Premium £2,050.

Full Schedule of Terms and Conditions will be forwarded on application.

No. 3699 SATURDAY, NOVEMBER 28, 1931 Price 1/3

The Serum Treatment of Ulcerative Colitis

THE researches of Bargen and his co-workers at the Mayo Clinic on ulcerative colitis led them to advance the view that a non-haemolytic streptococcus is the factor of primary etiological importance in this disease. Later work has done much to confirm the original findings.

In consequence, it has been possible to develop a specific Ulcerative Colitis Anti-streptococcus Serum which has been used clinically with very favourable results.

In the preparation of this serum Parke, Davis & Co. follow the method developed by Bargen, and have the advantage of using fresh cultures supplied by Bargen himself.

The dose of the serum should not be more than 2 c.c. to commence with, and this may be increased up to 5 c.c., injected either intramuscularly or intravenously, at intervals of 12 hours.

ULCERATIVE COLITIS ANTISTREPTOCOCCUS SERUM (P., D. & Co.)

Supplied in vials of 20 c.c. Further particulars will be sent on request.

PARKE, DAVIS & CO., 50 BEAK STREET, LONDON, W.1.

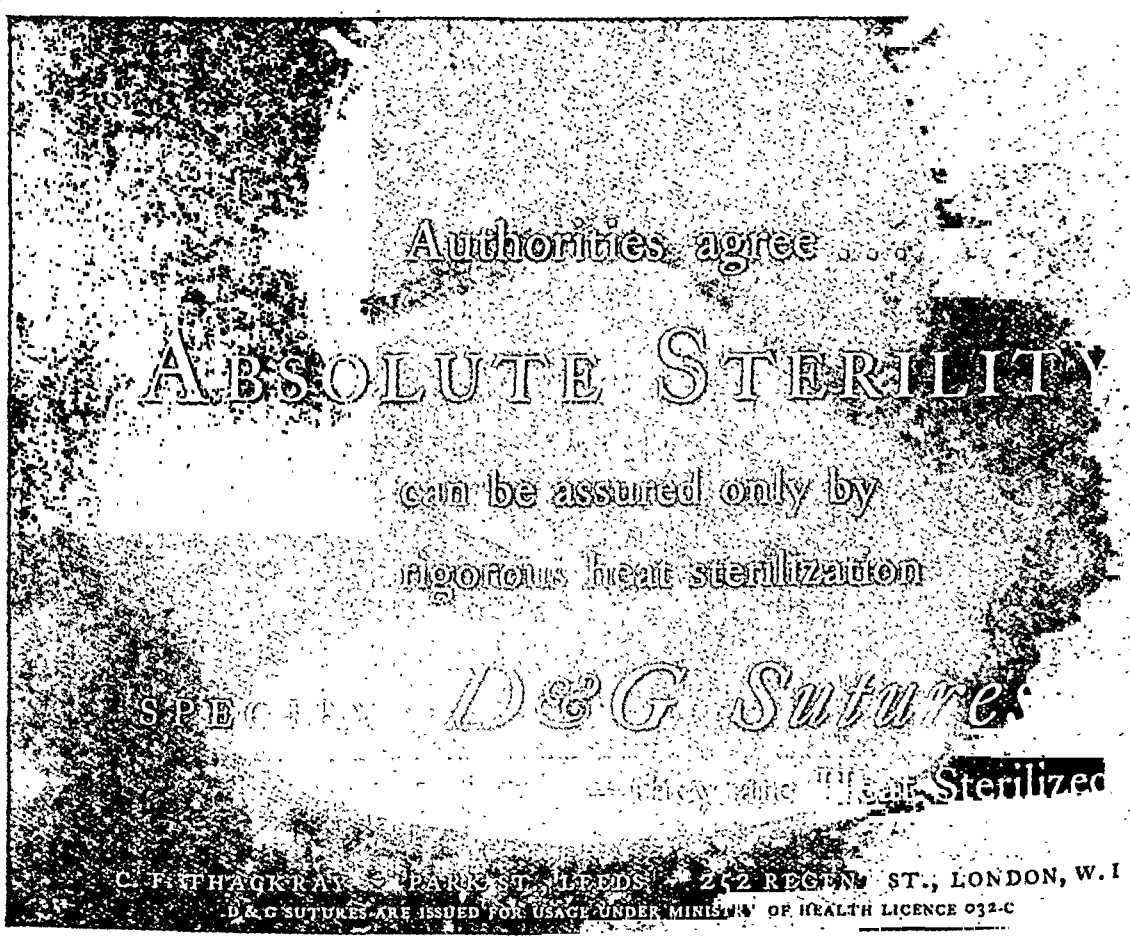
The Therapeutic value of BRANDY–

its lifting and sustaining powers—as compared with other spirits depends on the presence or absence of the higher Alcohols or Ethers. These in turn depend on Grape, Soil, Stills employed, Climate, Storage, Selection and Experience.

It is quite easy to make a spirit from grape wine—It is neither easy nor cheap to make a Brandy containing the qualities you want.



Cognac Brandy alone provides them.

Take no risks;
ensure the results you expect

Prescribe Brandy distilled in Pot Stills from Wines grown in the best Cognac districts; Matured in warehouses which have been filled with Cognac Brandy for centuries; Made by Men with the inherited Experience of Seven Generations.

In short—Prescribe
MARTELL'S BRANDY

and know that you are doing the best possible for your patients.

By DUNCAN C. L. FITZWILLIAMS, C.M.G., F.R.C.S. 4 Coloured Plates and 68 other Illustrations. Demy 8vo. 12s. 6d. net; postage 6d.

"... the case records give an idea of the success the author has had in many fields with the use of radium."—BRITISH JOURNAL OF SURGERY.

London: H. K. LEWIS & CO. LTD., 136 Gower Street and 24 Gower Place, W.C.1

Chemical Embryology

By JOSEPH NEEDHAM

Demy 8vo. In three volumes

With 15 plates (frontispiece in photogravure) and 9 tables 105s. net

This book is designed to fill a remarkable gap in the list of biological monographs. Embryology has hitherto been considered as a branch of morphology or anatomy, its functional and chemical aspects have been neglected. But the importance of an accurate knowledge of the physico-chemical events at all the stages of embryonic life is very considerable.

Dr. Needham who is University Demonstrator in Biochemistry, has collated the results of all previous work on the subject.

CAMBRIDGE UNIVERSITY PRESS

"Should be in the possession of every medical man."—*Glasgow Medical Journal*

URINARY SURGERY

A HANDBOOK FOR THE GENERAL PRACTITIONER

By W. K. IRWIN, M.D., F.R.C.S.,

Surgeon St. Paul's Hospital for Genito-Urinary Diseases

"Clearly written ... furnishes the practitioner with information of great practical value in his everyday work."—*British Medical Journal*

Genial Heat for Chilly Days

Facts about THE TILLEY RADIATOR

Height 14 in.

Doctors prescribe and consulting rooms, waiting, hospital wards, are pleasantly warmed by the TILLEY PADIATOR at a cost of but one penny for six hours. Burns paraffin and requires no connections, forming British all through.

THE TILLEY RADIATOR

can be carried with a handle and will burn long enough for evening in living room, bedroom or nursery, so that *the Radiator provides central heat and there is no need to pay three times as much for electricity.* Absolutely safe and cannot explode. No wick to adjust, and can be relighted in a small minute. Polished top is made of pierced copper, the mantle is strong and lasts well.

The price of the Tilley Radiator as illustrated is 40/-. Enquire Local Ironmonger. If any difficulty, Radiator will be sent post free on receipt of remittance, or C.O.D., postage and carriage paid.

For large rooms we make a Radiator with two burners—twice the heat—write for particulars. Lamps for the home also supplied.

THE TILLEY LAMP CO. (Dept. 14)

HENDON, N.W.4.

Name Plates

Write for our new list to W. H. LEE, Ltd., and designs and prices of BRASS, PHOSPHOR BRONZE, and CHROMIUM PLATED Name Plates (the latter are specially recommended), with full particulars and illustrations of Sketches are also sent, and can be executed in the shortest time on the Premises.

Special Number

December 5th

THE issue of the *British Medical Journal*, dated December 5th, 1931, will be the half-yearly Special Number. Its contents will include the full text of the Mitchell Banks Memorial Lecture on the "Problem of the Stiff Joint"; articles on the forthcoming Centenary Meeting of the British Medical Association; and the first of a series of historical notes on the work and progress of the Association from its foundation in 1832 up to the present time. The illustrations accompanying four of the original articles in that issue will be reproduced on a special photogravure supplement.

Many firms offering products or services for the professional and personal needs of medical men and women in all branches of practice will co-operate on this occasion by the insertion of special announcements in the advertisement pages. It is perhaps unnecessary to remind the majority of readers that the advertisement pages of the *British Medical Journal* constitute a forum where information regarding the latest and best accessories to medical practice may always be found, and that careful study of these announcements is profitable as well as instructive.

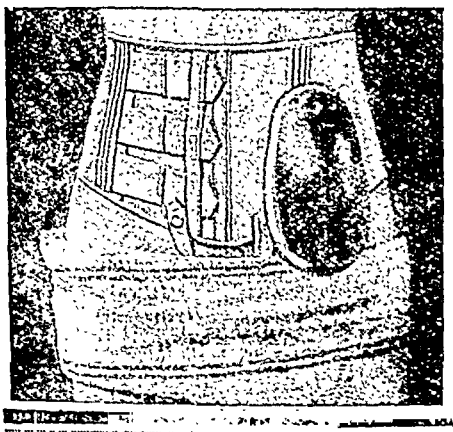
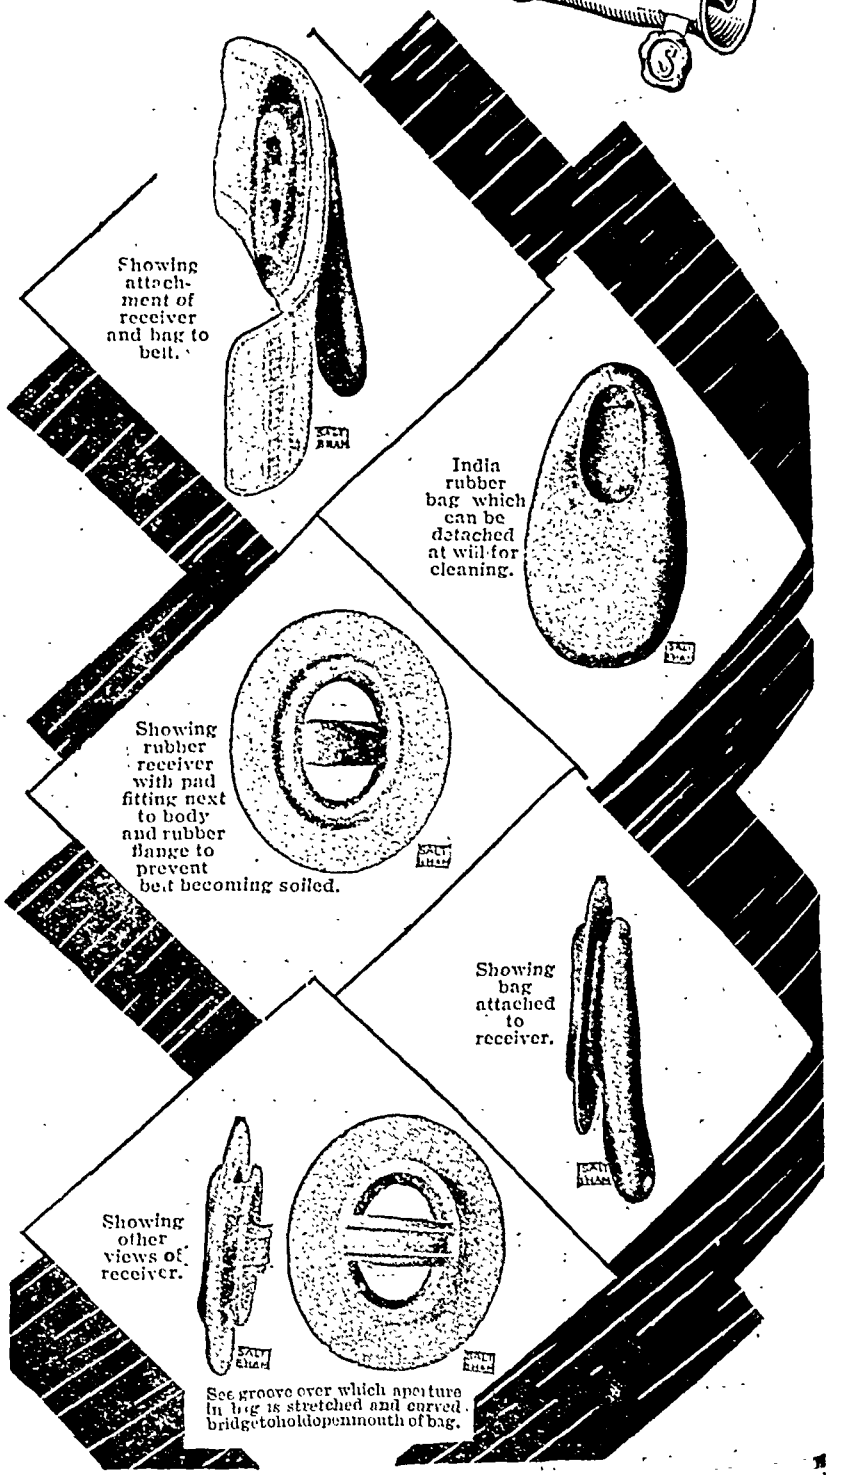
SALT'S PATENT COLOSTOMY BELT



The necessity of wearing a Colostomy Belt is an ever present source of embarrassment to the patient.



All undue apprehension on the patient's part is, however, largely overcome by the personal comfort and hygiene afforded by Salt's Colostomy Belt.

Note these advantages:—

1. Moulded rubber receiver, sterilizable by boiling.
2. Mouth of Bag kept open for free entry of Faeces.
3. Easy removal and cleaning of Bag without removal of Belt.
4. No crevices to hold Faeces, and therefore little odour.
5. Less bulky and more sanitary than any other.
6. Rubber portions far more durable than in the old style of belt.

N.B.—A belt is also made with special cup instead of bag for cases where the faeces are of a more solid nature.

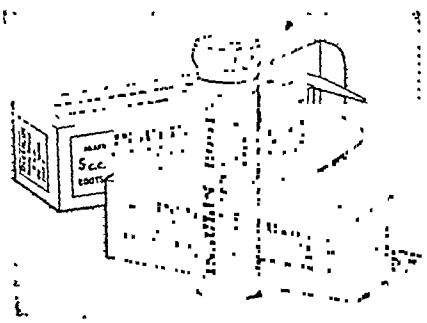
INSULIN (BOOTS)

INSULIN (BOOTS) is prepared in the Laboratories of Boots Pure Drug Company Ltd., under Licence No. 19 (Therapeutic Substances Act, 1925) of the Ministry of Health.



It is made from selected ox pancreas which is subject to the strictest examination before use.

The company possesses specially equipped Analytical, Pharmacological and Bacteriological Laboratories in which all the tests required by the Therapeutic Substances Act are carried out.

Each batch of Insulin (Boots) is tested for potency against the International Standard Insulin and also for sterility—these tests being carried out both before and after filling into ampoules. A sample of each batch, together with a report on the potency and bacteriological tests made, are submitted to the British Medical Research Council whose certificate of correct strength and of sterility is obtained before the batch is issued.

BRITISH

DRUGS

A 100% BRITISH PRODUCT

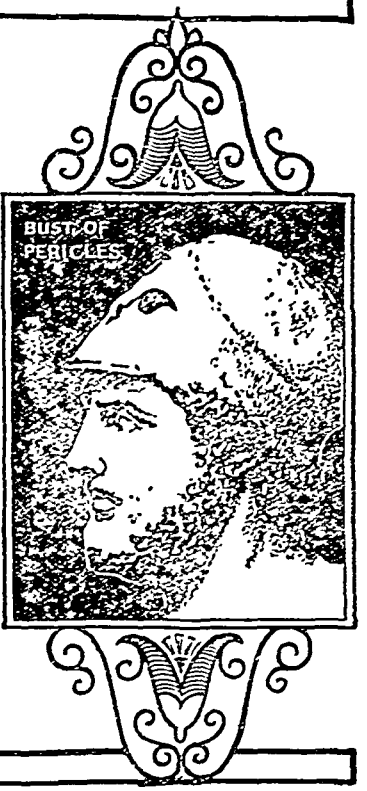
DIMOL LABORATORIES LTD.,
40, Ludgate Hill, London, E.C.4.

It frequently occurs that a member of the profession is given the opportunity of choosing between two articles, one the product of British research and labour, the other foreign, both of which are equally good in themselves. In such cases there should be no doubt which to choose.

DIMOL

(Dimethylomethoxyphenol)

The safest and most reliable non-toxic bactericide for all pathogenic conditions associated with an intestinal focus.



Bowel Inertia

THE Physician is familiar with the patient who complains of headache, loss of appetite, depression, who is not suffering pain but is nevertheless conscious that his or her general health is far below the standard it should be.

Diagnosis often reveals auto-intoxication—the result of habitual constipation. The use of a suitable eliminant is indicated.

"Cristolax" proves exceptionally successful in such cases. It is composed of 50% of the purest medicinal paraffin in combination with 50% "Wander" Dry Malt Extract. The high diastase quality of the pure malt extract gives material assistance to the digestive process which is often impaired in this condition, whilst the oil content lubricates the intestinal tract, keeps the faeces soft, and ensures their complete expulsion.

A delicious preparation in a clean, convenient dry form for infants, children, and adults.

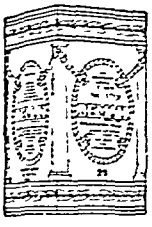
Has the Ordinary Diet Sufficient Vitamin B?

At the request of many correspondents a series of tests were recently conducted at the Bemax laboratories to determine how far the ordinary daily diet is an adequate source of Vitamin B.

The diet chosen for the tests included Eggs, Bacon, Bread, Butter, Beefsteak, Cabbage, Potatoes, Cheese, and a suitable percentage of A and D Vitamin.



The results prove conclusively that such a diet is in fact deficient in B Vitamin and cannot, by itself, meet the nutritional requirements of adults or promote normal growth in children.

Ample evidence is already available to show that partial B Vitamin deficiency results in a progressive deterioration of the digestive system, and may well be the principal cause of the many intestinal complaints which are so common to-day.

Bemax provides an ideal way of supplementing the ordinary diet with an adequate supply of B Vitamin, of which it is the richest known source in B_I, B_{II}, and B_{III}.

Its value as a tonic restorative food can hardly be over-estimated and its use has been attended with striking results in Dyspepsia, Constipation, Sleeplessness, Nervous Debility, Rheumatism, and all B deficiency diseases. As its content of E Vitamin is also exceptionally high it can be used with great advantage in the treatment of Sterility.

Medical Men are invited to write for reports of the tests referred to in this advertisement

Laboratory Reports on Bemax and Clinical Sample for personal trial will be sent to any Medical Man on request.

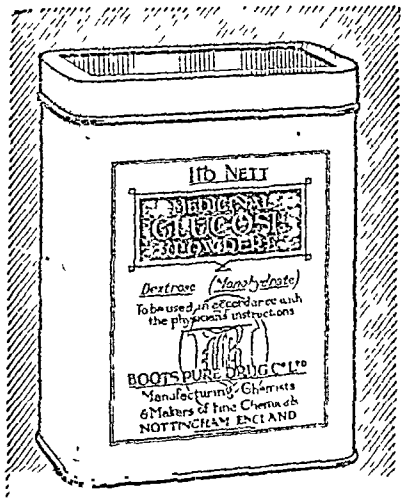
Cod-Liver Oil Cream

This ethical preparation is particularly acceptable to children. It may be prescribed with confidence that good results will be obtained.

Children take it readily, even where the usual difficulty has been experienced in inducing them to take other forms of Cod-Liver Oil. They rapidly respond to its nutritive and strengthening influence.

The Cream contains 50% of recently refined Cod-Liver Oil of high vitamin content. The fresh eggs used in the making enhance the value of the preparation as a nutrient. The Emulsion is perfect (vide *The Lancet*, Jan. 4th, 1930), rendering the assimilation easy, even in cases where digestion is weak.

The fact that it is freshly prepared every week ensures freedom from loss of vitamin efficiency of the oil, due to storage or exposure to sunlight.



The preparation is endorsed by many members of the Medical Profession.

4/-, 7/-, and 10/-, post free.

Immunity and Alkalinity

A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

appear, in the opinion of competent observers, to be in close relationship. At least it is certain that alkalinity is lowered in all infectious diseases, and that excess production or defective elimination of acid products lead to a number of metabolic disturbances.

To correct these conditions, present particularly in gastric and intestinal disorders, rheumatism, gout, and certain cutaneous affections, and to prevent their occurrence as a sequel to undue reduction of the buffer substances of the blood, prescribe

The reduction of

the incidence of

Puerperal Morbidity

Having in mind the fact that pregnant women are specially liable to develop gross signs of Vitamin A deficiency, and, further, that animals suffering from this deficiency . . . commonly develop chronic sepsis of the generative tract, four well-known investigators undertook recently an exhaustive series of experiments at two antenatal clinics in Sheffield.

Out of 550 pregnant women attending the two clinics 275 were treated with a Vitamin A preparation (RADIOSTOLEUM) whilst 275 were untreated. The published results *(B.M.J.,* Oct. 3rd, 1931, p. 595) show that, on the basis of the B.M.A. standard for puerperal morbidity, there were ***3 morbid cases*** only in the group of 275 women treated with RADIOSTOLEUM—an incidence of 1.1 per cent., whilst in the control group (untreated) there were ***13 morbid cases***—an incidence of 4.73 per cent., that is to say, more than four times as many as in the group treated with RADIOSTOLEUM.

RADIOSTOLEUM, *identical with that which caused a reduction of the incidence of puerperal morbidity from 4.73 per cent. to 1.1 per cent. in the Sheffield clinic,* is available from the principal pharmacists everywhere.

RADIOSTOLEUM

"EULAXASE"

For the

Rational Treatment of Constipation

"Eulaxase" is a new preparation, in tablet form, for the treatment of constipation. The tablets contain biliary and intestinal secretions, with agar-agar and lactic ferment (bacillus acidophilus), enclosed in a special coating of activated charcoal. The essential advantage of "Eulaxase" is that it provides a special substitute for each of the chief factors that are deficient in intestinal stasis. In other words, it forms a natural, complete, and efficient means of treatment for constipation.

In bottles of 60 tablets for prescribing, and 600 tablets for dispensing.

Descriptive leaflet will be sent on application.

VICHY-CÉLESTINS

Natural Mineral Water.

(And the other State Springs of Vichy.)

FERMENTATIVE DYSPEPSIA

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. **Vichy-Célestins,** by its slightly stimulating action, clears out the stomach, and this avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS:

INGRAM & ROYLE, LTD.

Bangor Wharf, 45, Belvedere Road, London, S.E.1

And at LIVERPOOL and BRISTOL.

Samples free to Members of the Medical Profession.

'PANOPEPTON'

AN IDEAL FOOD FOR INVALIDS.

Palatable—easy of administration. Lacking palatability, the most desirable of foods in other respects might be of no avail.

Agreeable—well retained, "even in the most desperate cases," to quote from a report.

Stimulating—of special service in low vitality.

Assimilable—perfectly and wholly assimilable, and gives th[illegible] at once the

Nourishing—benefit of every essential element of nutrition.

Supplied in 12-oz. bottles.

NOVOCAIN

The Original Preparation
English Trade Mark No. 276477 (1905)

Local Anæsthesia in Surgical Practice

UTERINE PROLAPSE

Typical Case.

Mrs. E. D. F., aged 53.

Diagnosis: Uterine prolapse, third degree with large vesicocele.

Operation: Watkin's interposition, perineorrhaphy.

Anaesthesia: Classical infiltration block using 45 c.c. of a 0.5 of 1 per cent. Novocain-Adrenaline solution in perineum. A circumferential block about the cervix was made using 30 c.c. of the same solution. The patient noticed some distress during delivery of the uterus into the vagina. The round ligaments were blocked as soon as they appeared, 4 c.c. of Novocain-Adrenaline solution being used in each case. The classical Watkin's operation was performed. The perineum was then repaired by the split septum method. Anaesthesia was ideal. Patient's pulse was 80 at the end of operation, and she had no post-operative nausea, vomiting or gas pains, and made an uneventful recovery.—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

The perfect LOCAL ANAESTHETIC *AT LAST*

● SELF-STERILISING. Novutox Local Anaesthetic is autogenously sterile and actually remains sterile for weeks after an ampoule or bottle is opened. Novutox can be stored in and used direct from a bottle, thus eliminating waste and economising both time and money.

• • ○ NOVUTOX BRAND LOCAL ANAESTHETIC *can be safely injected into infected infiltrated areas.*

● Read this extract from a letter recently received from a well-known surgeon:—

"I have given Novutox a thorough trial and am very pleased with it. In block anaesthesia over large areas the solution acts very well indeed. For instance, recently I excised the right testicle and cord in a man with active phthisis without his feeling any pain whatsoever. The solution seems to keep well and that is of considerable value."— B.Sc., M.Sc., M.B., Ch.B., F.R.C.S.

NOVUTOX BRAND LOCAL ANAESTHETIC

is not classed under the Dangerous Drugs Act and does not contain cocaine.

1. *Is seven times less toxic than cocaine.*
2. *Promotes quick and clean healing.*
3. *Ensures freedom from post-operative pains.*
4. *Gives deep and lasting anaesthesia.*
5. *Requires no preparation of any description.*

Prices direct or through usual wholesaler.

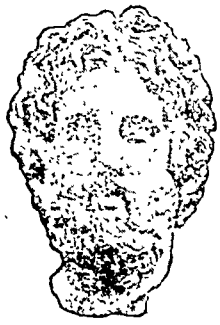
OSTOMALT

A palatable preparation of
VITAMINS A, B, C & D.

is a trustworthy supplementary source of vitamin C



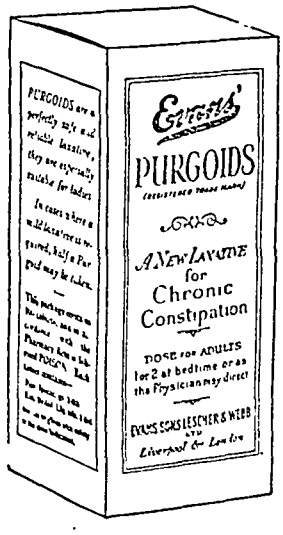
¶ *the claim is*

that Ostomalt "contains anti-scorbutic vitamin equivalent to half its volume of fresh orange juice."

¶ *official tests prove*

Official tests in an independent laboratory on a sample purchased in the open market found "very fair agreement" with this claim.

A trial jar of Ostomalt and full particulars of it will be sent, on request to:
GLAXO LABORATORIES, 56, Osnaburgh Street, LONDON, N.W.1



(*Æsculapius*).

PURGOIDS

PURGOIDS owe their unique laxative action to the correct balance of the formula which consists of Aloin, Phenolphthalein, Ipecacuanha, Belladonna, etc.

They promote peristalsis without causing griping or depression and they exert a distinct cathartic effect by increasing intestinal secretion.

The safety and comfort which attend their use render them of particular value to the nursing mother, as they have no harmful effect upon the child.

In addition to their use in constipation of long standing, Purgoids are to be commended as a general aperient in temporary conditions and after operations.

Issued in bottles of 25 and 100 Tablets and in bulk for dispensing.

DOSE: One or two Purgoids. Half Strength supplied for Children.

A Physician's sample will be sent with pleasure, on request.

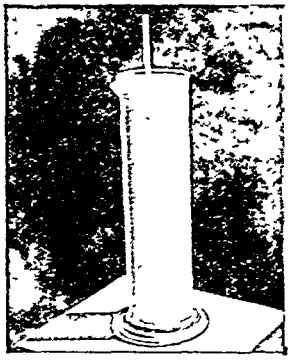
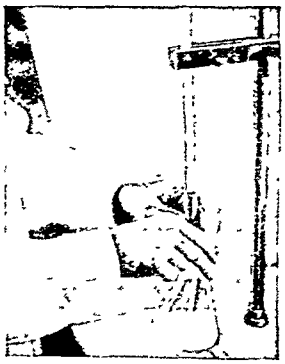
STANDARDIZATION OF THE INGREDIENTS OF THIS FAMOUS BRITISH PRODUCT



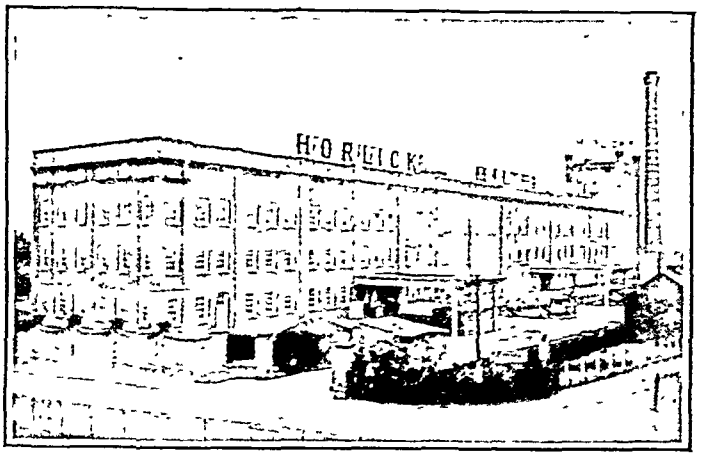
A general survey of milk testing done in the laboratory at Slough. Every batch of milk is tested for purity and richness before it leaves the producer, and then re-tested more strictly than ever by the Horlick experts. Three of the tests as shown below, are carried out, not once, but 3 or 4 times after arrival.

★



Determining the amount of fat present in the milk. The fat content of milk used in Horlick's Malted Milk is well above Government standards

★



A lactometer floating in a sample of milk. On it is registered specific gravity, from which can be calculated the amount of solids present

★

Testing for acidity. A measured quantity of milk is put into a glass vessel and neutralized with a standard chemical solution. This indicates the freshness of the milk and its suitability for use. If milk is too acid it cannot be heated or used for Horlick's

With Horlick's you can be sure you are prescribing an "ALL BRITISH" PRODUCT

HORLICK'S was originated half a century ago by an Englishman, Sir James Horlick, Bart., and year by year it has won ever-increasing popularity, until to-day it is confidently recommended by the medical profession all over the world.

Just now, when patriotic men and women are uniting their efforts to support home industries, it is particularly satisfactory for doctors and nurses to know that Horlick's Malted Milk is an "all British" product.

ENGLISH DAIRY FARMS SUPPLY THE FRESH FULL-CREAM MILK THAT GOES INTO HORLICK'S.

Cows fed on the richest pasture lands of England produce the fresh full-cream milk from which Horlick's is made. Barley from the eastern counties—malted at Horlick's own Maltings in Norfolk—and home-milled British wheat only are used in its manufacture.

BRITISH EMPLOYEES.

Horlick's Malted Milk Company, Ltd., is wholly English in Directorate and capital. From factory hand to skilled technician in the Laboratories and Test Rooms—**right through the organization British labour is employed.**

EVEN THE BOTTLES ARE BRITISH!

Only British material is used in Horlick's factory; even the bottles in which Horlick's is packed and the paper in which it is wrapped are **made in England.**

Horlick's Malted Milk Company, Ltd., Slough, Bucks.

Nutritional anaemia in infancy

IT has recently been shown that breast milk does not contain an adequate amount of iron and that from the early days of infancy it is necessary to supply iron to the organism, if healthy development of the child is to be attained.

The organic iron in Virol from Glycerine Extract of Red Bone Marrow and from yolk of eggs is absorbed with ease.

The vitamin-containing Fats are very finely emulsified; they are, therefore, easily digested by the most sensitive alimentary tract at all ages, including earliest infancy.

All experience goes to show that Virol is a food of marked value in a great variety of conditions in which adequate nutrition by ordinary means is not easy to secure.

Ephedrine Preparations

Consistently reliable

By prescribing 'Wellcome' Brand Ephedrine Preparations you ensure for your patients products of uniform composition and therapeutic activity.

Reduced facsimile

Those listed opposite are prepared from 'WELLCOME' Brand EPHEDRINE, the pure, natural lævo-rotatory alkaloid. It was this alkaloid which earned for ephedrine its reputation.

'Wellcome' Pseudoephedrine (*B.M.J.*, Nov. 14, 1931, *page* 906) is also available. Further particulars on application.

For Oral or Hypodermic use:

'TABLOID' EPHEDRINE HYDROCHLORIDE

Gr. 1/4 (0·016 gm.)
Bottles of 25 and 100, at 9d. and 2/3 each

Gr. 1/2 (0·032 gm.)
Bottles of 25 and 100, at 1/3 and 3/9 Tubes of 6, at 6d.

For local application to the Nose and Pharynx:

'EPINALIN'
SOLUTION OF ADRENALIN AND EPHEDRINE

Each c.c. contains Adrenalin, 0·0001 gramme (=1 in 10,000), and Ephedrine Sulphate, 0·02 gramme (=1 in 50)
Bottles of 10 c.c. and 25 c.c., at 1/1 and 2/3 each

'VAPOROLE' EPHEDRINE SPRAY COMPOUND

For use with an atomiser: Ephedrine, 1 per cent., Menthol, Camphor and Oil of Thyme of each 2 per cent., 'Paroleine' Liquid Paraffin, to 1 fl. oz.
Bottles of 1 fl. oz., at 2/3 each

For Oral Administration:

'ELIXOID' EPHEDRINE COMPOUND

Contains Ephedrine Hydrochloride, gr. 1/4, Syrup of Tolu, min. 15, Tincture of Virginian Prune, min. 2, and Chloroform, min. 1/8, in each fluid drachm
Bottles of 4 fl. oz. and 16 fl. oz., at 2,6 and 8/2 each

For Hypodermic Injection:

'HYPOLOID' EPHEDRINE HYDROCHLORIDE

0·03 gramme (gr. 1/2 approx.)
Boxes of 10, 1 c.c. phials, at 2/- per box

'HYPOLOID' & 'EPINALIN'
Hermetically-sealed containers of 1 c.c.
Boxes of 10, at 3/- per box

CALCIUM-SANDOZ

$(C_6H_{11}O_7)_2$ Ca.

Unique Advantages:

1.—It is effective. It supplies the physiologically active calcium ion.

2.—It shows distinct superiority in all modes of administration.

ORALLY: It is well absorbed. It is easily administered and does not upset the digestive tract.

INTRAVENOUSLY: It is better tolerated than calcium chloride. The acid-base factor is eliminated.

INTRAMUSCULARLY: It is painless and non-irritating. It is the only calcium salt which can be so administered in adequate doses.

3.—It enables physicians to adequately meet the requirements of any given case.

BY VEIN, for acute need.
BY MUSCLE, to secure intense and prolonged action.
BY MOUTH, for prolonged administration, to meet an increased demand by the organism.

4.—It is completely sufficient in itself as a therapeutic agent.

CALCIUM-SANDOZ is supplied in

Ampoules containing a 10% sterile solution for intravenous or intramuscular injection.
2 c.c. size: Boxes of 10 ampoules.
5 c.c. size: Boxes of 2 and 10 ampoules.
10 c.c. size: Boxes of 1, 5, and 20 ampoules.

Powder for oral administration.—Cartons of 2, 4, and 16 ounces.

Tablets for oral administration.—Each tablet contains 25 grains of calcium gluconate and is especially adapted for division into three parts. Boxes of 30 and 150 tablets. Cartons containing 12 boxes of 30 tablets.

* Included by Error

The number of cases notified in London has not diminished during the last fifteen years There was a considerable increase after the war, with a corresponding increase of patients seeking admission to St Margaret's Hospital The number of admissions of recent years has become a fairly constant factor The most striking point in the statistics is the amount of blindness, which has decreased by more than half as St Margaret's Hospital has become known and utilized

There are at present 218 children under 18 years of age on the roll of the L C C blind schools, of these, 45, a percentage of 20 6, are blind from ophthalmia neonatorum Although this is an enormous improvement on old statistics of blind institutions, it is probably still unduly high I believe that further improvement is possible by the proper teaching and training of midwives and medical students At the present time midwives receive a far better education on the subject than the medical student Classes are given at St Margaret's to midwives from Queen Charlotte's Hospital, the L C C, and other bodies The medical student receives no education in the subject, and probably never sees a case during his training I hope that this meeting will pass some sort of resolution which can be sent to the General Medical Council, drawing its attention to this fact as was done some years ago by the Council of British Ophthalmologists

The Eyes at Birth

When a child is born the eyelids are tightly closed, the skin being thrown into numerous wrinkles and covered with a fatty material The margins of the lids are usually in contact with each other, but occasionally the upper lid is found overlapping the lower As compared with the adult, the length of the palpebral aperture is small in comparison with the size of the conjunctival sac The lining membrane is thrown into numerous folds in the fornices and over the surface of the globe The margins of the lids are covered with fatty secretion from the Meibomian glands and with epithelial debris I have often found the Meibomian secretion containing the xerosis bacillus on the third day, and it is almost constantly present soon after birth It is probably derived from the vagina, and is almost certainly identical with the pseudo-diphtheritic bacillus found there No doubt the greasy secretion of the lid margins helps to prevent the infected vaginal discharge getting into the conjunctival sac, but probably more important is the rapid passage of the foetus through the vagina In one instance, in a case of twins, the first child was infected, whereas the second child escaped It is also possible that in this case the stretching of the perineum by the first child may have saved the second one

The epithelium of the ocular conjunctiva is not so thick as that of the adult but next to the epithelium covering the tarsus it is the thickest part of the epithelium of the conjunctiva at birth In the fornices at the bottom of the folds, the cells show signs of mucoid change to such an extent that the basement membrane is completely bare in places, and it would allow a ready entrance of organisms to the sub-conjunctival tissues The corneal epithelium is only about three cells in thickness, but to compensate for this there is a greater thickness of the substantia propria, in comparison both with the thickness of the sclera and with that of the adult cornea, this no doubt allows a freer circulation of lymph between the lamellae The conjunctiva and the corneal epithelium in the infant, therefore, do not offer the same resistance to infection as in the adult

At birth there is no lymphoid tissue in the conjunctiva After the first few days the lymphoid cells begin to appear generally around the vessels of the superficial layers in the superior fornices These cells gradually increase up to the fourth week of life, when the lymphoid layer seems to be fully formed The rapidity with which it forms depends on the amount of irritation the conjunctiva receives, thus, if nitrate of silver be applied at birth, the lymphoid cells appear in large numbers in forty eight hours

Histology of the Conjunctiva in Ophthalmia Neonatorum

The following observations were made on three cases of ophthalmia neonatorum They were all extremely severe cases, one had ended in complete destruction of both eyes, and the other two of one eye each The tissue was removed from the lower fornix in two of the cases, and from the upper fornix in one during the third week of the disease.

The epithelium on the surface is somewhat irregular in thickness, and is desquamating, some of the superficial cells containing the gonococcus The conjunctiva becomes papillated in consequence of the swelling beneath This is best seen in sections cut parallel to the surface, when papillae containing numerous blood vessels, and completely surrounded by epithelium, are observed The epithelial cells show evidence of mitosis, and are much separated from each other, chiefly, no doubt, by the passage through them of enormous numbers of polynuclear leucocytes, since the conjunctival sac often becomes filled with pus in less than five minutes after cleansing Between the epithelial cells are found numbers of mononuclear and polynuclear leucocytes The gonococci are found adherent to the cells With regard to the sub-epithelial tissue, there is an extensive exudation into the superficial layer of the connective tissue, the vessels in the deeper layer of connective tissue are dilated, and in and around the papillae there are quantities of small vessels of new formation with proliferating endothelium, these vessels contain large numbers of poly-

* Made in opening a discussion in the Section of Ophthalmology at the Annual Meeting of the British Medical Association, July 1931

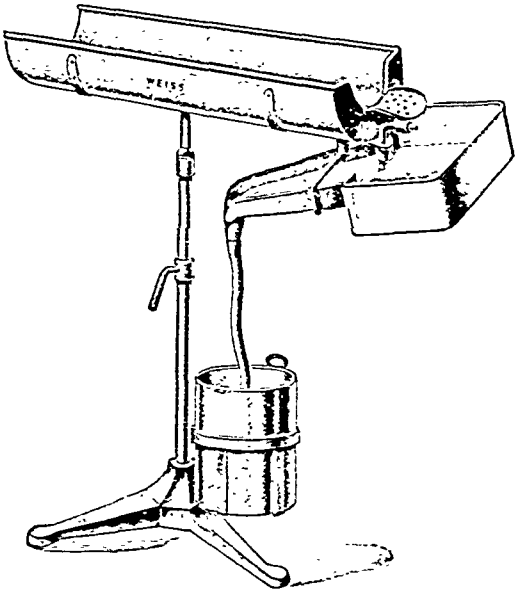
nuclear leucocytes, and show many beautiful examples of diapedesis. The connective-tissue cells of the superficial layer are found to be proliferating, but not to any marked extent. The cells in the deeper layer of connective tissue show practically no changes.

The cells of the exudation (polynuclear leucocytes), although they are found in large numbers in the sub-epithelial tissue, are not nearly so numerous as the mononuclear cells; their relative proportion becomes increased in the epithelium; in the discharge they make up about 94 per cent. of the cells. Hence it is seen that, although they constitute the greater proportion of the cells of the discharge, they are not seen in such enormous numbers in the sub-epithelial tissue as compared with the mononuclear cells—a fact which can easily be accounted for by their more active amoeboid movements. Mononuclear leucocytes, both large and small, are found in great numbers scattered throughout the exudation, and are seen best in the papillae, which contain little else but these cells, many of which are degenerating. Of great interest is the distribution of the plasma-cells in this disease. They are found in great numbers in the connective tissue beneath the papillae, but where they approach the epithelium they become rapidly broken up, the cells staining more faintly and losing their protoplasm; hence they are practically absent from the papillae, no doubt owing to the presence of the toxin produced by the gonococcus growing in the epithelium.

Bacteriology and Immunity

In St. Margaret's Hospital there have been no unusual organisms to record nor any variation in the usual percentage already described. The gonococcus occurs in between 60 and 65 per cent. of the cases. In the non-gonorrhoeal cases, the streptococcus is the only one of serious importance, in that it causes more severe inflammation than the gonococcus and frequently leads to perforation and panophthalmitis. Staphylococci, the Morax-Axenfeld bacillus, pneumococci, the Koch-Weeks bacillus, the Klebs-Loeffler bacillus, *Bacillus coli*, *Bacillus pyocyaneus*, have all been found. In about 10 per cent. of the cases no organism can be found in the discharge except, perhaps, the xerosis bacillus or the *Staphylococcus albus*. The former is present fairly constantly in all discharges, and the latter is frequently present, especially in association with the gonorrhoeal form.

The question of immunity to the gonococcus is of great interest and requires considerably more study than has been given to it. There seems little doubt that a general immunity to the gonococcus is extremely difficult to produce either clinically as the result of an attack of gonorrhoea, or artificially by vaccines. Patients who have an attack of gonorrhoea are by no means rendered immune to a second attack, or to local infection elsewhere in the body. For instance, a patient who has a gleet can infect his conjunctiva and produce a severe gonorrhoeal ophthalmia. Further, vaccines given in large doses seem to have no effect on ophthalmia neonatorum, although, perhaps, if continued over a long period they produce improvement in some chronic lesions such as iritis. At the same time, ophthalmia neonatorum clears up fairly rapidly and completely under local treatment except in a few instances. I do not think that this is entirely due to the application of antiseptics to the conjunctiva killing the organism, since it is found in large quantities even in the slight sticky discharge at the end of an attack. It may be that these organisms are of much lower virulence than the original organism found in the acute stage of the disease and hence gradually die out, but I think it is more probable that the disease clears up as the result of the local immunity which is produced in the conjunctiva. This question of local immunity has been very little investigated. Personally I think it is intimately bound up with the *monocellular* exudation which takes place after the acute stage of the inflammation begins to subside. The cell with which it is particularly associated is the plasma-cell, which always makes its appearance in enormous numbers as the acute inflammatory symptoms begin to resolve. Plasma-cells are broken up locally by the toxic products which are present at the seat of inflammation. It is possible by the breaking up of these cells that some antibodies may be liberated and so produce the local immunity.



We frequently see very severe attacks of gonorrhoeal ophthalmia in one eye and only a slight discharge in the other eye, yet the organism is found in both. I have also seen an acute recurrence in one eye after an interval of sixteen days, while the other eye was perfectly free from discharge, and yet the epithelial scraping in the sound eye showed the presence of the gonococcus. I suggest that this is due to the local immunity being greater in one eye than in the other. In some cases the local immunity in the conjunctiva is very slow to develop. Although there is nothing which is exactly comparable to gleet in the conjunctiva, we occasionally meet with cases which will not get well in spite of vigorous treatment, there being a little discharge which is full of organisms. We have had several cases in the hospital from three to five months; if sent out too soon these patients are very apt to relapse.

Institutional Treatment

In September, 1918, the Metropolitan Asylums Board opened St. Margaret's Hospital, Leighton Road, Kentish Town, consisting of 60 beds for women and infants, for the treatment of ophthalmia neonatorum. A theatre for the treatment of infants is provided; also a sterilizing room for disinfecting bowls, dressings, and feeding-bottles. There is a room and table for the treatment of mothers with vaginal discharge. A small bacteriological laboratory is attached, as every patient is bacteriologically examined immediately on admission. A day-room is provided where sewing can be done by the mothers when they get up; there are open-air wards for the babies whose mothers are not in hospital. A courtyard and a small garden, which are also very necessary adjuncts, are provided. In an institution of this kind it is essential to have separate lavatory accommodation for the gonorrhoeal and non-gonorrhoeal cases. A relatively large nursing staff is necessary, as the infants constantly want attention, and in addition to having their eyes washed out, they have to be washed, fed, kept clean, weighed, etc. The presence of the mother in the hospital is not such a great help in this respect, as they themselves require treatment; the infant is kept away from the mother in a separate cot except when it is actually being fed, therefore it requires almost the same amount of attention. Roughly, one nurse is needed for every two patients. Cots or cradles are provided for the infants. On the whole, perhaps, cradles are the most satisfactory, as plenty of fresh air is desirable to prevent the spread of infectious disease, and the high sides of the cots are apt to offer too much protection. The infant is always wrapped in a blanket so that it is not exposed when it is moved from its bed to the treatment-room to be irrigated. Hot bottles are usually kept in the cot in the winter time or when the child is ill. Fly-nets to cover the cots are very necessary in the summer. Tapes with the names of the children are fixed round their ankles so as to prevent any possibility of a mistake being made as to their identity.

Only gonorrhoeal cases receive treatment in the treatment-room. Non-gonorrhoeal patients are provided with sets of bowls and undines, and the treatment of these cases is carried out separately. They are as far as possible

nfined to one ward, but frequently this is not prac-
able, and isolation can be carried out in the wards as
ove described without risk of infection. For the irriga-
on and treatment of the infants' eyes a table has been
ade for me by Messrs. Weiss (see Fig.). It is of metal,
d it consists of a solid base with a central rod which can
raised or lowered by hand. The top consists of a trough,
t of which the baby cannot fall, and in one end of the
ough a half-moon-shaped piece is cut out so as to receive
e neck of the infant and prevent the soiling of the
othes from the lotion. Outside this is a curved adjust-
le head-piece on which the baby's head rests during
igation. Beneath the head-piece is a tray to catch the

ion, which is let off into a bucket of lysol fixed to the
nd. These are all easily removed for cleaning pur-
ses. The top of the table is slightly tilted towards the
ad.

Irrigation is carried out from an adjustable stand irriga-
r. Around the jar containing the lotion is a metal jacket,
nich in summer-time is packed with ice for cooling the
tion. A tap is provided to drain off the water from the
cket as the ice melts. A glass nozzle is attached to the
bber tubing from the irrigator. The nozzle is provided
th a ball stopcock, which can be adjusted with one
nd. When the nozzle is not in use it is kept in a solu-
on in a small jar attached to the stand. For the examina-
on of the cornea a focus lamp is adjusted over the face.
rotargol and other solutions are applied by wool mops and
ass rods. Only solutions are kept in undines.

Admission of Patients

The greatest difficulty we have to contend with is in get-
ng the patients into hospital early enough. The com-
onest time at which corneal ulceration occurs is during
e first stage of the disease. Although the law has drawn
e attention of the practitioners and midwives to its im-
ortance, there is often delay in the notification of the
sease to the medical officers of health. When the hospital
as first opened the average age at which the infant was
dmitted was three weeks, but this has since considerably
nproved as the attention of the health department has
en drawn to it, and now midwives are allowed to send
ses direct to the hospital without a medical certificate;
ut there is still too large a proportion of cases admitted
ith corneal ulceration. It is very difficult to make
octors and midwives realize that the mother and infant
can be moved safely by means of an ambulance on the
third or fourth day after the birth of the child; they do not
yet seem to grasp the importance of immediate and efficient
treatment.

Local Treatment

As soon as the patient is admitted to the hospital a
smear preparation is made from the conjunctival dis-
charge and stained with pyronin and methyl green or
thionin blue, and by Gram's method if necessary. It is
usually possible to make a diagnosis therefrom sufficient,
at any rate, to separate the gonorrhoeal from the non-
gonorrhoeal cases. If the gonococcus is found, the patient
is placed in the gonorrhoeal ward. The percentage of
gonorrhoeal cases admitted is a little higher than the general
average of 60 per cent.

In cases of doubt the patient is put in the isolation ward
and a smear preparation is taken on three or four succes-
sive days; cultures are also made, but as a rule the
latter do not afford much assistance in the diagnosis. If
the gonococcus is not found in three smear preparations
made on successive days, the patient is put in the "nega-
tive" ward. In the case of infants without their mothers
it is sometimes impossible to isolate the negative cases,
but the treatment of them can be quite safely carried out
in the ward without fear of infection. I may say here that
the word "gonorrhoea" is never mentioned in the hos-
pital, as it is apt to get the hospital the name of a
"venereal hospital" (which is extremely undesirable, as
it may lead to domestic trouble among the patients); to
get over this difficulty we therefore speak of the cases
as being positive and negative.

There is a special case paper showing the amount of
discharge present, which is recorded daily.

By comparative methods we have come to the conclusion
that eusol (1 in 10) is the best lotion to use, but it must
stand 24 hours after being made. The next best lotion is
one of boric acid and sodium bicarbonate. The lotion
is used every hour when the discharge is large in amount,
every two hours when less, and every three hours when
slight. After a wash out with the lotion the conjunctival
sac is filled with acriflavine (1 in 1,500 of castor oil). We
have found the use of this oil extremely beneficial. It
prevents the sticking of the eyelid margins, and it acts
as a harmless antiseptic constantly present in the conjunc-
tival sac. Our experience of silver applications is that
they seem to be of little value in the early stages of the
disease and inclined to accentuate the symptoms rather
than to improve them, so that they are not used, as a rule,
until the swelling of the eyelids begins to subside. They
are of the greatest value in clearing up the later stages
of the disease. All preparations are rubbed into the con-
junctiva with wool mops. The rubbing assists the removal
of the surface epithelium in which the organism is growing.
Nitrate of silver (10 grains to the ounce), subsequently
neutralized by a salt solution, is most efficient in skilful
hands. Where it is at all doubtful that the solution will
be properly applied, it is far safer to use 10 per cent.
protargol.

I think the use of silver nitrate for prophylactic treat-
ment is strongly to be deprecated, likewise the use of
mercury perchloride lotion. Every year there are ad-
mitted to St. Margaret's Hospital cases in which the cornea
has been damaged by the improper use of these drugs, and
personally I advise the use of acriflavine oil or protargol,
both of which, I think, are efficacious.

External canthotomy is done in the early stages of the
disease when the lids are greatly swollen, or when the
palpebral aperture is so small that the conjunctiva cannot
be properly cleansed. It prevents the retention of the pus
in the conjunctival sac under the pressure of the eyelids
and relieves the tissue tension by a local blood-letting.

Effect of Vaccine on the Disease

We have used ordinary and detoxicated vaccines extensively, and also serum, but I do not think that they have any influence in shortening the ordinary period of the disease. Treatment by milk injection has no effect, and is very dangerous, as the rise of temperature lowers the resistance, and is often associated with the onset of corneal ulceration.

Discharging of Patients

It is very difficult to know when a baby should be discharged from the hospital. Bacteriological examination has shown that the gonococcus can be found in the conjunctiva twenty-eight days after cessation of all the discharge. In our hospital we have had a relapse of the disease twenty-one days after cessation of all discharge, the eyelids during that time being not even sticky (the gonococcus was found in the recurrent discharge). It is obvious from a practical point of view that a child cannot be retained in the hospital for three weeks after the disease has apparently ceased, and it is the usual practice to discharge the patient after he has been totally free from any sign of discharge for a week. As a practical method this works fairly well. Strict injunction is given to the mothers to return if there is any sign of recurrence of the discharge. About 10 per cent. of the patients do so, and in most instances they are re-admitted. The gonococcus can always be found in considerable numbers even if the discharge is slight in amount. The relapse is hardly ever severe, and usually amounts only to stickiness of the lids. Every now and then a case may exhibit symptoms almost as acute as those of the early stages of the primary disease, but differing from it in that it only lasts for a very short time—usually about a week. I have never seen any corneal trouble as the result of recurrent attacks.

General Treatment

The general health of the infants is of the utmost importance, and one cannot emphasize too strongly the great care that is necessary in the feeding and management of them. There is an enormous contrast between the infants who are breast-fed and those who are admitted without their mothers. The infants who are admitted with their mothers, as a rule, do extremely well, and in spite of the constant disturbances due to treatment put on weight steadily. Infants admitted without mothers in most instances do not do nearly so well. This does not seem to be due to any variety of artificial feeding, as all the various dried milks, fresh milk direct from the country, and pep[illegible]ed milk have been tried without result. It is probable attack[illegible] the case of the infants who are nursed by their [illegible]to a sec[illegible]ome protection is afforded them through the breast-[illegible]at in[illegible]. Fo[illegible]here is little doubt that the infants do far better [illegible]others s[illegible]junc[illegible]r than in the summer, and the ophthalmia is [illegible]eeding. [illegible] Fu[illegible]hen. The infants who are admitted without [illegible] the wint[illegible] effect. [illegible]ot so severe [illegible] continue very largely drawn from the lowest class [illegible]heir mothers are [illegible]n som[illegible] frequently illegitimate, or the mothers [illegible]f patients, and are [illegible]ophth[illegible]me into the hospital because they [illegible]ay be unable to c[illegible]letely have a number of other children. [illegible]re obliged to work or [illegible] do not naturely born, and therefore the [illegible], large number are pre[illegible]antiseptic high amongst this class of case. [illegible]eath rate is always very [illegible]is found infants, if present, usually [illegible]ongenital syphilis in your[illegible]ge at may be very detrimental to [illegible]ows no signs, although it [illegible]ms are[illegible]nt, and is, I think, thereby [illegible]e general nutrition of the infa[illegible]found [illegible]tion. Congenital syphilis [illegible] frequent cause of corneal ulcera[illegible]y die these infants. In a series [illegible]oes not seem very prevalent in t[illegible]e clea[illegible]he blood was examined [illegible] twelve successive cases in which t[illegible]oduce Wassermann reaction. [illegible] case was found to have a positi[illegible]ty. [illegible]patients who developed [illegible] the [illegible]

corneal ulceration in the hospital, from clear corne[illegible], h[illegible] had a positive Wassermann. Many of the other cas[illegible] corneal ulceration have also shown a positive reaction.

Affections of the Cornea

The cornea is affected either by becoming hazy o[illegible] ulcerated.

In the early stages corneal haze is probably only d[illegible] to oedema in the corneal epithelium, but when the co[illegible] is very "hazy," especially when it is localized, it is p[illegible]ably the early stages of true infection of the cornea. Th[illegible] cases very frequently break down into corneal ulcers.

Corneal ulcers are of three types:

(a) Those which I call puncture ulcers, in which th[illegible] is a tiny perforation straight through the substance [illegible] the cornea with very little infiltration, which will deve[illegible] and run its course to perforation in twenty-four to forty-eight hours, subsequently leading to a very slight n.b.[illegible] possibly with an anterior polar cataract or adherent iri[illegible] The infection is always gonorrhoeal and the child in g[illegible] health.

(b) A fairly large ulcer with considerable infiltration [illegible] the cornea. In the early stages these may present them[illegible]selves as accumulations of pus beneath the epithelium or [illegible] a breaking-down hazy cornea. They frequently perforate, leading to dense nebulae with an adherent iris.

(c) Sloughing of the whole of the cornea. This ty[illegible] of ulcer is usually associated with marasmic or premat[illegible] children, and generally starts with very dense infiltrat[illegible] of the whole of the cornea, a central portion of wh[illegible] becomes necrotic and breaks down. Extrusion of the l[illegible] through the opening is frequent. It is these cases wh[illegible] lead to a staphylomatous cornea. Extrusion of the l[illegible] can only occur when the ulcer is very large an[illegible] involves the central portion of the cornea. I h[illegible] watched the extrusion in these cases. The umbo of t[illegible] lens presents in the base of the ulcer as the result of t[illegible] child's crying or straining, the lens is delivered thro[illegible] the ulcer, and generally remains attached by a few fib[illegible] of the suspensory ligament, which are then torn thro[illegible] by the closure of the eyelids, and the vitreous can b[illegible] clearly seen presenting in the wound.

In every case I have examined the lens is delivered [illegible] the capsule. In all cases in which the lens has been e[illegible] truded it has been followed by buphthalmos. Thi[illegible] probably due to the vitreous and iris being incorpora[illegible] in the wound and causing complete obliteration of t[illegible] anterior chamber. When there is streptococcal infect[illegible] this type of ulcer frequently leads to panophthalmitis, b[illegible] I have never seen a case of gonorrhoeal perforation go [illegible] to panophthalmitis, even where the lens is extruded a[illegible] the vitreous is presenting in the wound.

After-treatment of Corneal Ulceration

After the patients leave the hospital they are direct[illegible] to attend an ophthalmic hospital. Corneal nebulae, e[illegible] when they are quite dense, often clear very considera[illegible] and I do not advise any operation in the way of an op[illegible] iridectomy until the child is at least six months old, [illegible] it is impossible to say to what extent the corneal re[illegible] will clear. The chief indication for operation is nystagm[illegible] This develops directly the child is able to open his e[illegible] and look round for the light, and it is in these cases th[illegible] early operation is advisable. It is sometimes clear[illegible] in one eye affected by severe nebula when the other [illegible] is clear. My own experience of optical iridectomy, ex[illegible] in a few cases, is that the vision is not very greatly [illegible] proved thereby. On the other hand, in cases of ant[illegible] polar cataract where the cataract practically fills the [illegible]

its contracted condition, or in a small centrally situated bulk, the vision is often improved by a small optical lectomy, and in some instances this may be combined th the division of an adhesion of the iris to the posterior rface of the cornea I do not as a rule advise the iple division of anterior synechiae, as from my own exrience I do not think that they often give rise to much ouble For staphylomatous cornea and buphthalmic es which are protruding between the lid or which are ry unsightly, a Mule's operation is advisable, using a all glass ball, and stitching the sclera together with a rse string suture of silk, a separate stitch being made the conjunctiva If this method is followed, extrusion the ball is extremely rare.

Other Complications

Gonorrhoeal arthritis, although not uncommon in the others, is rare in the babies We have had only one h case in 350 children This child had both ankles l knee joints severely affected and subsequently died of art failure

Rhinitis is a frequent accompaniment of ophthalmia onatorum The gonococcus can be found in the nose en there is a large quantity of discharge, or when there practically none If there is much discharge there are ays immense quantities of other organisms, and I think t the rhinitis is attributable far more to these organ is than to the gonococcus

Purulent mucocele is often mistaken for ophthalmia onatorum In some of these cases the gonococcus has n found in the discharge, although the pneumococcus nore frequent

ME OBSERVATIONS ON THE CONTROL OF MEASLES EPIDEMICS

BY

PERCY STOCKS, M.D., D.P.H.

READER IN MEDICAL STATISTICS IN THE UNIVERSITY OF LONDON

e opinion is often expressed that measles epidemics not be controlled The basis for this view seems to that isolation is generally useless because the harm is ually done before the diagnosis is made, and that ool closure is neither practicable nor effective in pressing an epidemic Dr. Forbes, medical officer of lth for Brighton, has recently suggested that the exsion of home contacts attending infected schools might o be abandoned In view of advances which have been de in our knowledge of the epidemiology of measles seems worth while to ask ourselves how far epidemics 'd be modified, if it were so desired, by applying the owledge we now have

n an article[1] entitled "The mechanism of a measles demic," published in April of last year, I expressed the w that "the only hope of really preventing these demics altogether is through the immunity factor," and it "we must hope for either a simple method of culation which will produce a more or less permanent munity, or else a simple method of rendering an attack ortive and harmless, such as the proposed method of culating contacts with their parent's blood, whilst at same time allowing it to produce a permanent immunity." Considerable research has been done recently the experimental production of passive immunity in ldren by the use of human convalescent serum, and this s well summarized in the recent Report of the Medical icer of Health and School Medical Officer on the asles Epidemic of 1929-30 (London County Council, 31), and amplified by Dr. D. N. Nabarro and A. G. Signy in their paper in the *Journal*[2] In their series of 625 children treated with human serum before the fifth day after exposure to measles infection, only twelve developed measles, as compared with an expectation of several hundreds, and all the cases were mild in form The passive immunity produced in this way lasts, we are told, two to four weeks If the serum is injected on the sixth to the ninth day after exposure to infection partial protection is afforded, an attenuated attack resulting, which produces permanent active immunity.

Serum Protection in Relation to Epidemics

Provided that the serum is available, we now have a means, therefore, of protecting all home contacts to measles cases for upwards of a month, or, better still, of rendering them permanently immune by allowing them to have an attenuated attack Moreover, we could, if so desired, suppress an epidemic in any school by treating all unprotected children with convalescent serum, but in this case scarcely any of the treated children would receive anything but a temporary passive immunity, and since an epidemic lasts several months the school would probably be again invaded by measles when this immunity had waned and before the infectiousness had declined to the normal level There are, of course, practical difficulties in the way of any such operations on a large scale—in particular, the difficulty of obtaining sufficient serum and of overcoming prejudice against such a procedure—but it is by no means unlikely that these difficulties may be removed It is not, therefore, merely a matter of academic interest to estimate what effect could be produced on a measles epidemic by giving certain groups of children a passive immunity at a certain phase of the epidemic

The first question to ask is What groups of children should be immunized in order to produce the maximal salutary effect? Some light is thrown upon this by the figures in Table I, which were obtained from an analysis of the card records of measles notifications in the metropolitan borough of Battersea during 1925-28 (This was made possible by the courtesy of the medical officer of health, Dr. G. Quin Lennane.) The table shows the ages of 486 children under 9 years of age who contracted measles from another child in the same house, developing the rash ten to thirteen days later than the first child These I have termed "secondary cases," and the age of the child from whom the disease was contracted, termed the "primary case," is also shown in each instance It is readily seen from the table that the secondary cases are, on the whole, much younger than the primary cases, actually the mean age of the primaries is 5·3 years, and 60 per cent are aged 5 or over, compared with 3·2 years and 17 per cent for the secondaries.

TABLE I

Age of primary case	Ages of secondary Case									Total
	0-1	1-2	2-3	3-4	4-5	5-6	6-7	7-8	8-9	
0-1	—	—	2	3	1	2	—	—	—	8

Total ...	48	111	93	85	61	34	21	8	19	486

In Fig. 1 the contrast is shown more clearly, and it is evident that the chief culprits in taking home infection to their brothers and sisters are the 5-year-olds. At the foot of the diagram is shown the age distribution of the 176 children who contracted measles at home from these

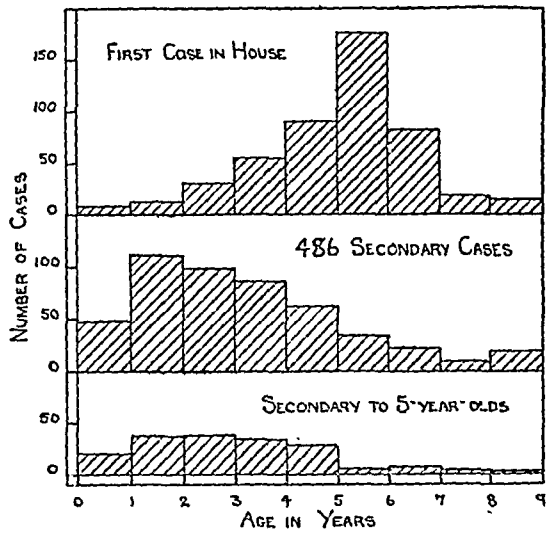

Fig. 1.—Age distribution of primary and secondary measles cases in households in Battersea, 1925-28.

5-year-olds; 137 of them, or more than three-quarters, were of ages 1, 2, 3, or 4 years. In the present paper I shall only attempt to estimate the effect of producing temporary passive immunity by means of convalescent serum or parent's serum, in two groups of children who have never had measles—(1) all home contacts to measles cases, (2) all 5-year-old children—these being the most obvious groups to deal with in any attempt to modify an epidemic.

Effect of Immunizing Home Contacts

In Fig. 2 is shown the mean curve of measles incidence in Battersea, obtained by tabulating the numbers of notified cases in successive periods of ten days in each

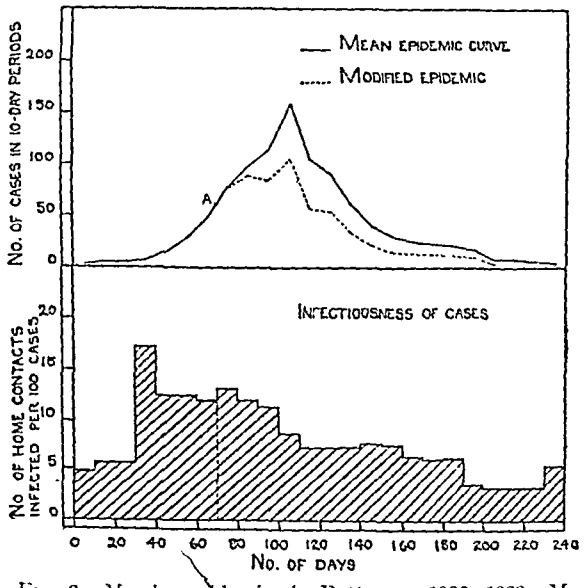

Fig. 2.—Measles epidemics in Battersea, 1926, 1928. Mean trend of incidence and infectiousness in nine districts.

of the nine wards of the borough and in two epidemics of 1926 and 1928. The eighteen small epidemics, averaging about 500 cases in each, were then made synchronous by bringing all the "peaks" of the curves, or periods of ten days having the maximum incidence, together, and then summing the cases in corresponding periods as measured forwards and backwards from the peak period. As I have shown from St. Pancras data,[3] measles epidemics move across the map, each district producing its epidemic curve of similar form and duration, but starting at different times as determined by a sudden upset in the balance between infectiousness and immunity factors; hence to obtain a typical curve it is necessary to proceed in this way. The curve in Fig. 2 is compiled from 8,649 cases, and the frequencies reduced to a total of 1,000 cases in 240 days—(namely, the peak period of ten days, ten periods preceding and thirteen periods succeeding it). In the lower portion is shown the ratio of the number of secondary cases which follow ten to thirteen days later in the same houses to the total incidence of cases, this being a measure of the "apparent infectiousness"[4] of the disease at the time of infection. This shows that a sudden rise in apparent infectiousness takes place at the very start of the epidemic, and it then gradually falls to a low value by the end of the epidemic. The details of total incidence and secondary cases are given in the first few columns of Table II, and in the fifth column is shown the incidence reduced to a total of 1,000.

Supposing that in a district where a measles epidemic of 1,000 cases is to be expected from previous experience,

Table II

Periods of Ten Days		Total Incidence	No. of Secondary Cases to these	Ratio per cent.	Incidence in Epidemic of 1,000	No. Aged 5	Expected Result of Immunizing all 5-years-old		
							No. Suppressed		Persons Infected

as soon as the incidence has risen to 50 cases in ten days that is at point A, about the seventieth day on the time scale in Fig. 2, every home contact who has never had measles is immunized within five days from appearance of the rash in the primary case, and that this is continued until the epidemic is over, what would be the effect? Every secondary case below the dotted line in Table II would be suppressed, a total of 673 cases in 3

total epidemic of 8,649, or 78 cases in a total epidemic of 1,000. The "secondary" cases as here defined would be accompanied by about half as many others with incubation periods of fourteen to eighteen days[4] who would also escape, making 117 in all. Owing to the practice of keeping contacts at home during the infective period it may be assumed that they would not have infected other children outside their own houses, and hence the total effect would be limited to reducing the epidemic from 1,000 to 883. A few of the 117 children might contract measles from outside sources before the epidemic was over, owing to the rapid loss of their temporary passive immunity, but the vast majority of them would escape for another two years (in London), and would have the advantage of being then subject to less danger of mortality owing to their greater age. Thus the fatality rate in St. Pancras was shown to fall from 7 at age 1 year to 1.2 at 3 years, and from 2.9 at 2 years to 0.6 at 4 years of age. If the immunization were carried out on the seventh day after the rash appeared in the primary case instead of earlier, these 117 children would have attenuated attacks and become permanently immune, a much more satisfactory result under ordinary circumstances. We may roughly estimate how many home contacts would have to be immunized by serum in order to produce this salutary result on 117 children as follows. From St. Pancras data of the 1926 epidemic 80 per cent. of children under 7 who had not previously had measles, and who were living in houses where at least one case occurred, were attacked, including both the primary and the secondary cases. In an epidemic totalling 1,000 cases, from Table II, 91 × 1.5, or 136, would be secondary cases after ten to eighteen days' interval, and 864 would be first cases in houses. The number of children under 7 at risk before the epidemic, assuming the St. Pancras figures to apply to Battersea, would be 950/.8 = 1,188, and deducting those of the 864 primary cases who were under 7, estimated at 821, there would be 367 home contacts under 7 years of age who had not had measles, of whom 129 would be expected to contract the disease immediately. In our district producing an epidemic of 1,000 cases the number of home contacts to be immunized after the point A in Fig. 2 would be therefore about 350, and the total result of this work would be either to delay or to attenuate the attack in one-third of them.

Effect of Immunizing All 5-year-old Children

Let us now suppose that at point A on the curve in Fig. 2, that is when the incidence in ten days has exceeded 5 per cent. of the total size of the epidemic expected from previous experience, all the 5-year-old children who have not had measles are immunized. It is known that the passive immunity produced falls to a level which is ineffective in stopping an attack after two to four weeks—that is to say, in some children it will have fallen to this level in two weeks and in others not until four weeks have elapsed. The rate of fall of artificially produced immunity to various organisms has been experimentally studied in a few instances, and it seems reasonable to infer that the fall in passive immunity begins at once, and takes place at a uniform rate.

Herrman[5] found that after the second month of age the percentages of children (of mothers who had at some time had measles) who exhibited immunity to measles infection were in successive months of age as follows: 95, 90, 75, 55, 34, 12, 5. These figures indicate, it is believed, the loss of passive immunity derived in the first instance by the infant through the placental circulation, and it is to be expected that passive immunity artificially produced by serum injections will be lost in a similar manner—that is to say, by almost equal decrements in equal units of time, as in the diagram (Fig. 3).

In this diagram the amount of passive immunity is represented on a vertical scale, being zero at O, sufficient at B to render an attack mild, and at C just sufficient to suppress it altogether. Under normal conditions there can be few, if any, children with sufficient inherent passive immunity to suppress an attack of measles completely, but since many mild attacks occur, it is no doubt present in some children to an extent exceeding OB, though not to an extent approaching OC, as represented in the left-hand side of the diagram. Injection of convalescent serum at point A must raise the level in all the children well above the C level, but not to the same height in all, and it may be assumed that the subsequent behaviour of

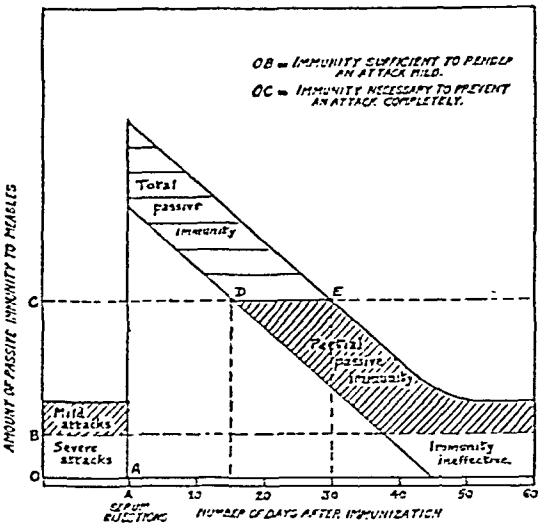

Fig. 3.—Diagrammatic representation of the probable effect of treating a group of children with measles convalescent serum.

a large group of children simultaneously immunized at A will be represented by the shaded band. During the first fifteen days all will be totally immune to infection; between fifteen and thirty days an increasing number will lose their total immunity and have only a partial immunity leading to attenuated or mild attacks if infected during this period; from thirty to about forty days all of them will have this partial immunity, but after about fifty days they will have returned to the original distribution.

The effect of immunizing the 5-year-olds at A on the epidemic curve of Fig. 2 can now be estimated, and is shown in Table II and by the dotted line in Fig. 2. The assumptions made for simplicity are that the incubation period is ten to fifteen days; that infections received more than nine days before serum treatment at A would be unaffected by it; that infections received six to nine days before A would result in mild attacks, and those received in the period from five days before A to fifteen days after A would all be suppressed; that infections received at any point after fifteen days would be suppressed or attenuated in the proportions indicated on a vertical line erected in Fig. 3 at that point of time. Thus infections received between fifteen and twenty days on the time scale would result in complete suppression in about 80 per cent., and attenuation in 20 per cent., and these deductions must be made from the cases which would have arisen in the undisturbed epidemic ten to fifteen days later—namely, between twenty-five and thirty-five days after serum treatment. Proceeding

in this way, the numbers of 5-year-olds saved from measles attack would, as shown in Table II, amount to 78 out of a total of 221. In addition, about 35 would have mild attacks instead of severe attacks.

Assuming that all the "primary" cases really arise by infection from some other primary case ten to fifteen days before, it is an easy matter to calculate the number of children who would subsequently be saved from measles by the suppression of the 78 5-year-old sources of infection, by multiplying the number suppressed in a given period by the ratio of new cases arising in a period ten to fifteen days later to those arising in the period in question according to the epidemic curve. Thus the 7 cases suppressed ten to twenty days after the point A would have been expected to give rise to 135/96 times 7 fresh cases developing in the period twenty-five to thirty-five days after A, or 5 cases in the period twenty to thirty and 5 in the period thirty to forty. These 10 cases would again be expected to have given rise to others further on, which can be calculated in the same way. Thus the chain of 215 children who would be indirectly saved from measles attack is arrived at, giving a total of 293 cases suppressed out of 1,000. The modification of the epidemic curve thus produced is shown by the dotted line in Fig. 2.

In this calculation it is of course assumed that the children thus saved from measles would not contract infections from other sources than those which have been removed, and also takes no account of the fact that the epidemic might by such interference be merely prolonged until almost the full 1,000 children had been attacked. This last event is not an unlikely one if the theory of the natural termination of epidemics of measles through temporary latent active immunization of the bulk of the child population is correct. Nevertheless, the calculation serves to show the utmost possible effect which might be produced through treating all the 5-year-olds who had not had measles with serum in the early stages of an epidemic. The number who would have to be so treated may be estimated thus. From St. Pancras data[1] it appears that the number of 5-year-old children at risk at the start of an epidemic is approximately equal to the total children of all ages who are subsequently attacked in the epidemic, and on this basis there would be about 900 requiring immunization at point A, the utmost result of this being to delay the attack of measles, by two years perhaps, in about 300 children.

Conclusions

The immunization of all home contacts with convalescent or parent's serum is therefore the more practical procedure, and the more certain in its results, but the total volume of an epidemic could not be reduced by more than about 13 per cent. by this means, and only about one-third of the injections would have any useful effect at all.

The second method, the immunization of all children of certain ages who have not had measles, is more problematical in its results, but presents the theoretical possibility at least of reducing an epidemic temporarily to any proportions desired, though probably only thus making inevitable a larger epidemic at a later date.

There remains another possible method of procedure which may provide the solution—namely, artificially to expose children of certain ages to measles infection, and also give them a partial immunity. Herrman advocated and carried out the inoculation of infants before they had lost their maternally derived immunity by applying the nasal discharge from a measles case to the nasal mucous membrane of children in the fifth month of age. This has the disadvantage that they may infect their older brothers and sisters in the mild attack which follows, though if adopted as a routine practice this would soon cease to occur, since they would all have been previously immunized. A better method, suggested I think by Zingher, is to apply the virus to the nasal mucous membrane of rather older children, and several days later inject convalescent serum subcutaneously so as to ensure a mild attack and permanent active immunization.

Such inoculation from child to child is of course open to serious objections, but more natural though less certain methods of exposure could be substituted. For instance, we have heard of "measles tea parties" and frowned upon them, but when coupled with subsequent artificial immunization they would cease to be barbarous, and become humane. Perhaps 50 per cent. would respond to such exposure in the way desired; the remainder would escape infection for a year or two by the combined protection of active latent immunity and artificially produced passive immunity, and would have to be either left to their own devices, or given another chance some two years later. There is no theoretical reason why by applying some variety of this method systematically measles epidemics could not be completely controlled or done away with as we know them, and the mortality and harmful sequels reduced to a negligible quantity.

Towards the expenses of research on the Battersea records, of which use has been made in this paper, a grant was made by the British Medical Association.

A NOTE ON SEPTICAEMIA*

BY

SIR W. I. DE C. WHEELER

The largest contribution which surgery has made towards the treatment of septicaemia is in the field of prophylaxis. A discussion on prophylaxis would revolve naturally round Listerism, but it is too wide a sphere for a meeting such as this.

A few weak links in the prophylactic chain are worthy of consideration. We know, for example, that if there is a discoverable focus of infection which can be adequately dealt with, the infected blood stream usually takes care of itself and the prognosis becomes good. The search for this microbic fountain may tax all our resources; it may be found in the gall-bladder or in the root of a tooth. The onset of septicaemia is often traceable to the injudicious management of a primary focus—for example, early incision or milking of an abscess near the lips is attended by real danger. I have known of four deaths from such interference. I have also seen a fatal case of acute septicaemia following injury by a razor to a septic pimple on the face. Rowlands mentioned a case of septicaemia following the too free incision of a furuncle in the external ear. By too early incision of a facial focus a rich plexus of veins may be wounded; the organisms enter the opened venous radicles and are carried via the facial vein to the cavernous sinus, with fatal results. Again, death from general sepsis may follow prostatectomy in cases which have been treated beforehand by radiation. It seems probable that the epithelium of the rectum occasionally is so injured by

* Introductory remarks in a joint discussion in the Sections of Medicine and Surgery at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

radiation of the prostate that organisms permeate from its interior into the space from which the gland has been removed The raw prostatic bed is a suitable incubator, and violent sepsis may result I have had experience of two such cases Thus we learn the necessity of caution in dealing with a primary focus After the onset of general infection, abscesses may form in any situation, their discovery and evacuation is often the signal of recovery

As pre technique in the operating theatre may be of a high order, but the best efforts may be nullified if nurses and assistants in charge of, or in contact with, septic cases are part of the team I have had a case of *Streptococcus haemolyticus* septicaemia after a simple appendicectomy which was traceable to a nurse who, when not in the theatre, was in charge of a septic gynaecological case in an adjoining room Again, epidemics of septicaemia have been traced to the throats of asymptomatic carriers when there was laxity about masking all those within the reach of operative work We cannot yet claim that prophylactic measures in surgery have reached perfection

Remarks on Treatment

Surgeons physicians, and biochemists see many cases of septicaemia without discoverable cause, and the treatment of this group is in consequence not satisfactory What is the best line of treatment in a case with a positive blood culture? Assuming that there is no accessible primary focus, and that the organism is the streptococcus, serum should be employed Fifty cubic centimetres of the unvalent form given intravenously on three consecutive days has been suggested by Horder The results of serum therapy justify immediate and adequate dosage Should we employ intravenous injections of such substances as mercurochrome and gentian violet? The literature in favour of these and allied remedies is interesting There are strong advocates for this line of treatment My own practice has been to use mercurochrome, 20 c cm of a 1 per cent solution intravenously on two or three consecutive days when everything else had been tried without success, but I am not convinced that intravenous injections of any antiseptic are useful Horder recommends arsenic as the most useful drug Colebrook states that in the treatment of syphilis by the salvarsan group the blood serum becomes a destructor of streptococci and that the leucocytes remain unaffected There is therefore a prima facie case for the more extended use of arsenic in septicaemic conditions Blood transfusions have little or no direct effect in the control of sepsis, indirect benefit may be derived in the more chronic cases

Large quantities of fluid given intravenously and by the rectal and subcutaneous routes are always beneficial, and 3,000 to 4,000 c cm daily of 10 per cent dextrose solution in normal saline may be given continuously by the drip method through a cannula in the internal saphenous vein without disturbance to the patient, or in divided doses through a needle into the veins of the arm The patient is thus fed, the glycogen reserve of the liver is raised, the heart is stimulated, and diuresis is increased Tap water can be administered simultaneously by the drip method into the rectum, or saline into the subcutaneous tissues of the breast Such methods assist in the dilution and elimination of toxins Murphy's arguments in favour of ample fluids were not confined to cases of septic peritonitis

Finally, treatment of septicaemic cases in the open air when practicable should be employed There is no comparison between the results of treatment of local sepsis in an open air hospital and in a city hospital In like manner, patients suffering from infection of the blood stream respond to treatment better in the open air

OCULAR COMPLICATIONS OF CHRONIC EPIDEMIC ENCEPHALITIS*

BY

THEODORE H WHITTINGTON, M D, M R C P, D O M S

CHIEF OPHTHALMIC ASSISTANT, KING'S COLLEGE HOSPITAL; OPHTHALMIC SURGEON QUEEN MARY'S HOSPITAL AND SOUTH EASTER HOSPITAL FOR CHILDREN CONSULTING OCULIST POST ENCEPHALITIS UNIT, LONDON COUNTY COUNCIL

During the last six years I have been examining cases at the post encephalitis lethargica unit of the London County Council, at the Northern Hospital, Winchmore Hill It was felt, therefore, that some remarks on the ocular conditions met with, based on notes of 174 cases of the later stages of the disease in children, might be of interest, and that it might be well to review the subject briefly from the ophthalmological standpoint in the light of more recent knowledge and longer experience

Ophthalmologists are interested in epidemic encephalitis (or encephalitis lethargica, so called) for many reasons, which can be summarized thus (1) As regards the diagnosis of the disease, the ocular phenomena being of great importance in this respect, both in the acute and chronic stages (2) On account of the peculiarity of these ocular signs, some of the most extraordinary of which occur only in this disease (3) Because the correlation of these ocular phenomena with the known pathology of the disease helps to throw further light on the neurology of some of the ocular movements, and is closely related to the subject we have been discussing† in this Section—namely, ocular palsies (4) Lastly, because the great benefit obtained in chronic encephalitic Parkinsonism by the use of the belladonna group of drugs is now well recognized As a result, the ophthalmologist is called on to counteract the visual disabilities which may be produced by this treatment

Ocular Signs in the Acute Stage

You scarcely need to be reminded of the importance of the ocular signs and symptoms of the acute stage which result principally from varied kinds of ophthalmoplegia There are the transient nerve root paralyses giving rise to transient diplopia, and, as I shall suggest, to the ptosis There are the irregular ophthalmoplegias due to deeper lesions, resulting in altered movements of the eyeballs, defects in the movements of the pupils, and peculiarities in the movements of the lids In the Ministry of Health Report No 11,[1] 78 per cent of the patients, in a series of 1,152 case reports, had the external ocular muscles affected in some way or another Thus, ptosis occurred in nearly 50 per cent, squint in 34 per cent, diplopia without obvious squint in 18 per cent, and nystagmus in 18 per cent

In the acute stage epidemic encephalitis presents multitudinous symptoms, and may, and does, simulate many diseases of the brain I would suggest, however that there are two common types with which particularly, the ophthalmologist may meet The first is a type showing ocular disturbances occurring in a febrile disease with marked disorder of sleep The second is that of a so called "influenza" with diplopia—a milder type often missed, but equally liable to sequels

It should also be added that the presence of papilloedema or of optic neuritis is decidedly against the diagnosis of encephalitis

Ocular Signs in the Chronic Stage

One can contrast these ocular complications of the acute stage with those seen in the chronic stage It has been

* Paper read in the Section of Ophthalmology at the Annual Meeting of the British Medical Association at Edinburgh, 1931.
† See report *British Medical Journal*, August 8, 1931, p. 250.

said that, in proportion to the comparatively small number attacked, there is probably no infection or contagious disease in this country which produces so much consequent ill-health and disablement as does encephalitis lethargica. My experience has been mostly with children suffering from the sequels of behaviour disorder and post-encephalitic Parkinsonism. Generally speaking, the impression one has received is that the ocular signs and symptoms so commonly present at the onset and during the acute stages of the disease are comparatively rare in the post-encephalitic stage.[2] Statistics may be summarized as follows:

Number examined: 174 (boys 113, girls 61).

Average age when first examined: 11 years.

Average date of onset of disease: 3 years previously (6 months to 9 years).

Number of cases with ptosis (one or both sides): 11 (6 per cent.).

Number of cases with weak convergence or tendency to divergence: 25 (13 per cent. plus).

Number of cases with concomitant external strabismus: 26 (about 15 per cent.).

Number of cases with concomitant vertical strabismus: 2.

Number of cases with paralysis of internal rectus muscle: 1.

*Pupils: Very slight or absent reaction to accommodation, 47 (27 per cent.); direct light reflex very slight or absent, 23.

Cases having oculogyric crises: 6.

The points to be noted in these statistics are: (1) the infrequency of ptosis; (2) the number of cases with diminished or absent pupil reactions; (3) the absence of paralytic squint, but the remarkable number with concomitant external strabismus or some form of divergence (28 per cent.); and (4) the onset of oculogyric crises.

Ptosis

Ptosis would appear, therefore, to be the result of lymphocytic inflammation in the acute stage, affecting the third nerve as it passes out from the surface of the crus. This explains why the ptosis disappears as the acute stage dies down. We know, too, that when some only of the third nerve branches are affected by lesions in this situation, the branch to the levator palpebrae is the one most frequently affected. This explanation is supported by the fact that I have never seen an example of Benedikt's syndrome in the numerous chronic encephalitics in whom the red nucleus appears to be affected.

Abnormalities of the Pupil

The pupil abnormalities are due to active disease of the third nerve nucleus or of its connexions. Some patients developed abnormal pupils two or three years after I had noted them as normal. Arising in the occipital cortex, there are some fibres in the optic radiations which take an opposite course to the majority, and become detached from the optic tract to pass through the crus to the third nerve nucleus. These may be considered as afferent branches to the sphincter pupillae and ciliary muscle. As the substantia nigra and the tegmentum are areas particularly affected in chronic encephalitis,[3] these fibres may well be affected in this part of their course. We have to remember, also, that the size of the pupil is the resultant of opposing forces actuated by the sympathetic and third nerve, and that in chronic epidemic encephalitis the sympathetic system is in an irritable and partially uncontrolled state as the result of lesions in the corpus striatum and optic thalamus. Lastly, convergence is largely a voluntary act and a late development in the history of the human eyes, and the higher control of the lower centres in the mid-brain is markedly affected in this disease.

Herein to some extent may lie the explanation of the form of squint common in these children. Binocular vision is not firmly established until childhood is well advanced, and in the presence of weak convergence these children tend to get concomitant external strabismus.

Oculogyric Crisis

The oculogyric crises are peculiar to the Parkinsonian form of this disease. In all the cases I have seen there has been spasmodic conjugate movement of the eyes upwards, commonly slightly to one or other side, lasting from a minute to many hours. The patient is conscious of the condition and finds it distressing. He may tell you that his eyes go up and he cannot get them down, or that they won't stay down, as sometimes by an effort he can bring them down for a moment. In a bad Parkinsonian case which I have observed in an adult, the eyes were completely rolled up, the jaw was fixed, with the mouth open, the head remained firmly set in the Parkinsonian forward position, and there was a respiratory crisis, making the patient cyanosed. In some patients the eyes do not go right up, but get fixed only slightly above the horizontal, or complaint is made of staring and that the eyes get fixed on an object. It is important for these mild cases to be recognized, and for their symptoms to be remembered by ophthalmologists and not considered hysterical or "functional," especially as these patients tend to be emotional. These crises come on from one to eight years after the original acute illness, and may occur in persons leading more or less normal lives,[4] and so be the first clue to the onset of the post-encephalitic state.[5] Hence their extreme importance in diagnosis and prognosis, as sooner or later definite Parkinsonism develops. In two adult cases which I examined, the fixing of the eyes was the chief symptom in the early stages. Periodic outbursts of uncontrolled behaviour, either of excitement or grief, may be associated with the crises in adolescents.[6] Such cases can usually be much controlled by hyoscine or stramonium, whereas this is not so in the acute behaviour disorders not associated with the ocular crises. The onset of the crises points to an activity of the disease, and would appear to indicate danger of psychotic symptoms. In a series of 136 cases which eventually had to be certified, 17 per cent. had oculogyric crises.[7]

It is impossible in a short time to discuss fully the site of the lesions causing these weird attacks. We can see, however, how they fit in with the general conception that many of the appearances of the post-encephalitic state are largely "release" phenomena. Professor Elliot Smith, in his address on the evolution of the instruments of vision at Oxford,[11] showed a photograph of an anthropoid ape. The semi-erect stance, with the head and shoulders bent forwards, with the arms hanging extended so that the hands were level with the knees, the expressionless face with the dropped lower jaw, together vividly reminded me of the general appearance of many adolescents with severe Parkinsonism. In this disease the mid-brain[8] (particularly the substantia nigra and the corpus striatum, closely connected by the strio-nigral tract[9]) shows most signs of the disease, and so the connecting links for central control over the extra-pyramidal system are affected. Also, irritative lesions of the more primitive centres[10] in the basal nuclei may occur at the same time as the more recently developed neo-striatum is deficient in controlling them. Dr. Edwin Bramwell[11] recently said

* Note: None of these patients were having drugs producing mydriasis. Only one case showed definite signs of previous congestion of an optic disk, an observation which supports the statement already made as to the rarity of disk changes in the disease. Six patients had oculogyric crises.

that he knows of no case where a fit characterized by upward or downward movement of the eyes was associated with disease of the cerebral hemispheres. There appears to be an innate co-ordinated upward movement of the eyes associated with the emotions, and related to a centre of a lower level. The eyes roll upward in sleep, and I have noted how in infancy, at an age when the vegetative centres are apt to take control, the eyes roll up in convulsions caused by gastro-intestinal irritation.

Other Ocular Symptoms

Other ocular symptoms noted among my patients are excessive blinking, fluttering of the eyelids, and difficulty in moving the eyes in a vertical direction when told to do so. I do not consider these typical of chronic encephalitis, but rather characteristic of the over-emotional state of the patients who show them. We have all observed them in emotional or nervous subjects—the act of blinking being closely related to the mental tension of the subject at the time.[12] Bradykinesis of Parkinsonism is often seen in slow carrying out of the normal voluntary movements of the eyes, and sometimes adds to the difficulties of reading.

Effects of Hyoscine and Stramonium

I now come to the last part of my subject—namely, the visual disabilities caused by hyoscine or stramonium in the treatment of Parkinsonism. Often ten times the pharmacopœial dose of stramonium is given, resulting in very marked improvement in the Parkinsonian rigidity.[13] Many of the patients, however, complain greatly of their inability to read, and of being worried by bright light, due to paresis of accommodation and dilatation of the pupils. Roughly speaking, the stramonium effect as regards accommodation for reading distance is counteracted by a + 1·50 to 1·75 lens, and eserine and pilocarpine applied to the conjunctival sac seems to counteract the effect to the extent of ¼ dioptres. Thus children and young adults with normal refraction, who do not want to read much, can have their visual disabilities removed by myotics. Presbyopes and hypermetropes need glasses, the latter for constant wear. In the case of children, or of adolescents who are myopes or whose mentality is such that they do not wish to read, or who have disorders of behaviour in which the use of glasses is inadvisable, the use of myotics to prevent dazzle is found the best procedure. I have had a group of twenty patients of all these varieties under various myotics; three have wished to continue with the use of pilocarpine drops rather than have glasses. The problem is a definite one, as it would appear that these Parkinsonian patients have to continue with stramonium for the rest of their lives.

These are but a few of the interesting points which have appealed to me as an ophthalmologist in dealing with these patients.

I should like to thank Dr Borthwick, the medical superintendent of the Northern Hospital, and Dr T. R. Hill, for facilities to examine these patients.

VESICAL SCHISTOSOMIASIS COMPLICATED BY CARCINOMA

BY

N. HAMILTON FAIRLEY, O.B.E., M.D., D.Sc., F.R.C.P.

ASSISTANT PHYSICIAN AND DIRECTOR OF PATHOLOGY, HOSPITAL FOR TROPICAL DISEASES, LONDON; LECTURER IN CLINICAL MEDICINE AND APPLIED PATHOLOGY, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

Vesical schistosomiasis is a disease with an unenviable history, for parasitic schistosomes may survive for long periods in the portal system, depositing ova from time to time in the pelvic viscera with cumulative effects. Accurate information on the longevity of the worms is limited, but Christopherson[1] (1924) recorded some important cases where viable ova were passed eighteen to twenty-eight years after patients had contracted their malady. The case recorded below is of special interest, as the duration of the disease was approximately thirty years, during the last twenty-nine of which the patient resided permanently in England.

A man, aged 50, first came to the out-patient department of the Hospital for Tropical Diseases, London, in October 1930, complaining of intermittent haematuria of approximately thirty years' duration which had developed during the South African war. Bilharzial infestation had been suspected.

The patient, who went to the South African war in 1900, was invalided to England in 1902 on account of debility and haematuria, which continued for about two years. Since that time the appearance of blood in the urine and vesical discomfort had been essentially intermittent; he only remembered three severe attacks of haematuria throughout the period, and he was often without symptoms for years. Two months before admission a severe relapse occurred, and then the haematuria had been persistent, but not to as great an extent as his thumb being passed in the urine. Onset of haematuria was terminal in onset, but later the bleeding continued throughout micturition. The urine on the first examination contained albumin and many red blood corpuscles, but no ova. The bilharzial skin test proved to be strongly positive, a wheal of 2·5 cm. diameter developing in a few minutes with the characteristic pseudopodial pale outrunners and surrounding erythema. The complement-fixation test was also strongly positive (++++), quantitative titrations showing a fixation of 12 minimal haemolytic doses of complement. Subsequent urinary examination revealed a few dead terminal spined ova of *Schistosoma haematobium*. The serological diagnosis of vesical schistosomiasis was thus confirmed.

At this time the patient was not prepared to come into hospital, though the possibilities of superadded renal disease and vesical carcinoma were pointed out. On November 6th, 1930, he returned for admission, complaining of fever, persistent haematuria with the passage of blood clots, strangury, penile irritation, aching pains across the hypogastrium and in the right groin. Loss of weight had recently been rapid, and during the previous fortnight he had suffered from profuse sweats. On admission the temperature was 103° F., the pulse 110, and the respirations 22 per minute. Asthma was also present; it originated during the South African war and had since been an annual occurrence.

On examination the patient was found to have distressed breathing and an asthmatic facies. Multiple telangiectases covered the cheeks. Ten round or oval-shaped nodules varying in size from 0·5 to 1·5 cm. in diameter, hard in consistency and somewhat bluish in colour, were noted in the subcutaneous tissues over the abdomen and chest. Under local anæsthesia one was removed for microscopical examination.

The tongue was furred, the teeth were carious and pyorrhœa was marked. The chest moved equally in the two sides, but the air entry was poor. A pleuritic rub was heard over the lower part of the right side of the chest anteriorly and to a lesser degree behind. The heart sounds were rapid and regular, but the peripheral blood vessels were not visibly affected.

VESICAL SCHISTOSOMIASIS COMPLICATED BY CARCINOMA

BY

N. HAMILTON FAIRLEY, O.B.E., M.D., D.Sc., F.R.C.P.

ASSISTANT PHYSICIAN AND DIRECTOR OF PATHOLOGY, HOSPITAL FOR TROPICAL DISEASES, LONDON; LECTURER IN CLINICAL MEDICINE AND APPLIED PATHOLOGY, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

Loss of weight had recently been rapid, and during the previous fortnight he had suffered from profuse sweats. On admission the temperature was 103° F., the pulse 110, and the respirations 22 per minute. Asthma was also present; it originated during the South African war and had since been an annual occurrence.

On examination the patient was found to have distressed breathing and an asthmatic facies. Multiple telangiectases covered the cheeks. Ten round or oval-shaped nodules varying in size from 0·5 to 1·5 cm. in diameter, hard in consistency and somewhat bluish in colour, were noted in the subcutaneous tissues over the abdomen and chest. Under local anæsthesia one was removed for microscopical examination.

The tongue was furred, the teeth were carious and pyorrhœa was marked. The chest moved equally in the two sides, but the air entry was poor. A pleuritic rub was heard over the lower part of the right side of the chest anteriorly and to a lesser degree behind. The heart sounds were rapid and regular, but the peripheral blood vessels were not visibly affected.

The blood pressure was 140/84. The liver was somewhat tender, and palpable one fingerbreadth below the costal margin. Tenderness was present in both iliac fossae, as well as in the loins.

The patient was too ill for cystoscopy, but a diagnosis of vesical carcinoma, with generalized carcinomatosis secondary to vesical schistosomiasis, was made. The following notes epitomize the progress of the case.

November 9th, 1930.—The patient was very ill, with a greyish-coloured facies and rapid pulse. Sibilant rhonchi were heard all over the lungs, and at the right base there was impaired resonance, with moist sounds behind and coarse friction sounds in front. The sputum was rusty, and contained pus and epithelial cells; examinations failed to reveal schistosome ova. The Wassermann reaction was negative, and the stools showed no ova or protozoa. The blood urea figure was 40 mg. per 100 c.cm.

November 14th.—Dyspnoea and cyanosis were present. There was a marked tricuspid systolic bruit associated with epigastric pulsation; tubular breathing, increased vocal resonance, and crepitations were noted at the right base.

November 15th.—Haematological investigations showed: erythrocytes, 4,700,000 per c.mm.; leucocytes, 13,000 per c.mm.; and haemoglobin, 80 per cent. The differential count was: neutrophils, 75 per cent.; lymphocytes, 14 per cent.; mononuclears, 5 per cent.; and eosinophils, 6 per cent.

November 16th.—There was progressive increase in the dyspnoea and cyanosis, and at times the former was paroxysmal. The right side of the heart was obviously engorged, and venesection was performed with temporary benefit. Oxygen, digitaline, and pituitrin were also administered. The blood pressure was 102/62, and the blood urea figure 64 mg. per 100 c.cm. The patient was semi-comatose and still cyanosed. The urine contained much albumin, with many erythrocytes, and fatty and hyaline casts; sugar and ketone bodies were absent. Glucose was given intravenously, and sodium bicarbonate and glucose by the rectum.

November 17th.—The patient appeared more comfortable. Moist rales were present over the right base, and tenderness was marked in both loins. The optic disks were normal. The blood urea was now 92 mg. per 100 c.cm., and the plasma CO_2 figure was 78.5 volumes per 100 c.cm. Lumbar puncture released clear cerebro-spinal fluid under increased pressure—250 mm. water pressure.

November 18th.—The patient was semi-comatose and cyanosed, with a dry mouth and rambling speech. Normal quantities of blood-stained urine were passed. At 1.30 a.m. the pulse rapidly weakened, and he died. The terminal picture rather resembled uraemia, but the urinary findings and blood chemistry did not support this diagnosis, and at the necropsy abundant functioning renal tissue was found.

Morbid Anatomy

The necropsy was performed nine hours after death. The patient was emaciated, and showed multiple subcutaneous carcinomatous nodules, while post-mortem staining was marked in the tissues of the back and buttocks.

Thorax.—The subpleural tissues were studded with carcinomatous nodules, some of which were umbilicated. The right lung showed extensive adhesions anteriorly and laterally; via these, direct cancerous infiltration of the intercostal muscles and of a pectoral lymph gland had occurred. The lower portion of the right lung was extensively consolidated. The heart presented little abnormality; no secondaries were found.

Abdomen.—The liver was slightly enlarged, and showed some increase of fibrous tissue around the periportal zones, as well as scanty carcinomatous nodules, ranging in size from 0.3 to 1.8 cm. in diameter. The gall-bladder was distended with bile, and there were carcinomatous glands in the portal fissure. The tail of the pancreas also contained carcinomatous deposits. A few squat circular nodules of secondary carcinoma were noted in the submucosa in the cardiac end of the stomach, as well as in the first part of the duodenum. No deposits were seen in the enterocolon, but carcinomatous involvement of some of the mesenteric and colonic lymph glands had occurred. The appendix was abnormally large, and a number of small subperitoneal nodules, the size of a pin's head, were present. The kidneys presented little evidence of fibrosis; the pelves were not dilated, and the ureters in their abdominal course showed no abnormality. Small white carcinomatous nodules were seen under the capsule. The cortex was narrow, but the capsule was smooth, and stripped readily. The suprarenals were enlarged and very hard, and showed extensive carcinomatous involvement.

The bladder was hard, contracted, and of small size. It was removed by an *en bloc* dissection, with the prostate, seminal vesicles, and terminal portion of the pelvic colon and rectum. On opening the bladder, carcinomatous ulcers, with extensive infiltration of the base and neck of the bladder, were demonstrated. The ulcers, on section, cut in a gritty fashion, suggesting that they originated in the sandy patches so characteristic of chronic vesical schistosomiasis. The mucous membrane also presented some squat papillomatous outgrowths, carcinomatous in nature. The seminal vesicles were thickened and hard, as were also the bases of the ureters where they passed through the vesical wall; this thickening extended for at least one inch of the extra-vesical portion of their course. The prostate was also involved, but the urethra was not obstructed.

Brain.—No haemorrhages or carcinomatous deposits were noted in the brain, but there was a marked excess of cerebro-spinal fluid in the pia-arachnoid space, and some degree of cerebral oedema.

Ova and Worms

Unfortunately the examination of the pelvic venous plexuses for schistosomes was postponed until after the pelvic viscera had been removed, and it was then found impossible to make satisfactory observations. Examination of the mesenteric veins, however, revealed a living male schistosome; other worms would undoubtedly have been demonstrated had the examination been made at the beginning instead of at the end of the necropsy.

Tissues from different organs were digested in 4 per cent. caustic soda solution for 20 hours at 55° C. Large quantities of ova were demonstrated in the sediment of the digest from the bladder and seminal vesicles; they were also found in smaller numbers in the large intestine, liver, and lung, but not in the pancreas and small intestine.

Microscopical Pathology

Microscopical sections showed epithelioma of the bladder, and a heavy deposit of schistosome ova confined to the mucosal and submucosal layers; the carcinomatous infiltration extended beyond these zones, deeply invading the muscular layers of the bladder. Some of the schistosome eggs contained normal miracidia, while others were dead and calcified. Ova were also noted in the muscular coats of the ureters, and there were heavy deposits in the seminal vesicles, where they were surrounded by whorls of fibrous tissue. Sections of the liver contained scanty ova, but there was a consistent increase in the fibrous tissue of Glisson's capsules, which sometimes showed small-celled infiltration. Considerable hepatic congestion was present, and nodules of secondary carcinoma were encountered. Secondary carcinomatous deposits were also studded in sections of the pancreas, suprarenals, and lungs.

Commentary

Vesical epithelioma is the common cancer of Egypt, and Ferguson[2] (1911) first recognized its essential relationship to deposits of bilharzial eggs in the bladder wall. It is generally regarded as supervening only in chronic cases which have been repeatedly exposed to infection over long periods of time, but the present case shows that continuous re-infection is unnecessary for its development. The experimental findings in *Rhesus* monkeys also support this view, for Fairley[3] (1920) described extensive bilharzial papillomatosis of the bladder some three months after heavy cercarial infection; even at this early date in certain of the sections the transition to malignancy was debatable.

Though cases of *S. haematobium* may undergo spontaneous cure with the passage of time, others in which the haematuria is mild or completely absent for years may develop vesical carcinoma and renal complications, owing to the steady deposit of ova in the bladder and

lower third of the ureters respectively. Further, secondary bacterial infection may complicate the picture at any time. For these reasons it cannot be too strongly emphasized that, in Europeans at least, bilharzial infestation should be diagnosed as early as possible and thoroughly treated. It is equally important to remember that cystoscopy, the complement-fixation test, and the intradermal skin test for schistosomiasis, may reveal infestation at a time when ova are not demonstrable in the urine or faeces.

Since 1900 this patient had passed through the hands of a number of practitioners; it is particularly unfortunate that his condition remained undiagnosed until carcinoma had supervened, for at an earlier date the intravenous administration of tartar emetic would have been curative.

SOME FACTORS IN THE REDUCTION OF ABSENTEEISM DUE TO CATARRHAL CONDITIONS

BY

T. E. A. STOWELL, M.D., F.R.C.S.

CHIEF MEDICAL OFFICER TO IMPERIAL CHEMICAL INDUSTRIES

The impairment of efficiency and earning capacity of the worker which is caused by mild ailments, especially catarrhal illnesses, is of such magnitude that no apology is needed for this brief report on some measures that have resulted in approximately a 50 per cent. reduction of absenteeism in the head offices of a large industrial undertaking.

In estimating the significance of the accompanying comparative table it should be remembered that the figures relating to the approved society do not include any absences from work of less than three days, while those relating to the industrial undertaking include absences of one day only.

There are several factors which contribute to the striking differences—for example, the healthy position of the building and its design, a system by which a good midday meal is available for the employees at a reasonable cost, and the encouragement of exercise by the provision of a well-equipped gymnasium and facilities for outdoor games. Also of great importance is the medical supervision of every member of the staff. The essence of this supervision is that every employee has easy access to the resident medical officer at certain hours of the day. Appointments are fixed beforehand by the matron, so that time spent in the doctor's waiting room is reduced to a minimum. All new employees are medically examined before they are engaged; so, too, are all employees who have been away from work on account of ill-health. Thus many minor defects are discovered, and advice given for their remedy before they have assumed such proportions as will lead to illness and its consequent wastefulness both to the patient and to the employer. Other important factors in the reduction of sickness have been: (1) ultra-violet ray medication; (2) remedial exercises prescribed by the medical officer, and taught by the gymnasium instructor after office hours; and (3) inoculation, both prophylactic and curative.

The high figure in Column B is accounted for by the fact that any employee reporting sick, with a slight rise of temperature, increased pulse rate, or other early symptoms of illness, is immediately sent home to bed and told to call in a private practitioner. A day or two in bed is more economical than the lengthy absence which may result from neglecting illness in its initial stages.

It is disturbing to note the very high absenteeism due to catarrhal conditions. The total percentage of employees

Sick Absence in the Offices of an Industrial Undertaking for the Year ended December 31st, 1930, compared with Figures supplied by a Similar Undertaking, and by an Approved Society consisting largely of Office Workers.

	Average Number Employed A	Percentage of Sick Absentees B	Average Amount of Sick Absence in Days per Person Employed C
Head office staff of the industrial undertaking	1,443	75.2	4.70
Staff of a similar large London office	2,256	63.5	9.15
Members of an approved society	2,401	No figure available	9.16

absent some time during the year suffering from all forms of sickness was 75.2, while the corresponding figure from catarrhal conditions was 51.625. Attempts to control the absenteeism due to this cause have met with some degree of success.

PROPHYLACTIC INOCULATION

This was offered to every member of the staff, and was an experiment in mass autogenous vaccine. During the preceding winter, cultures were taken from the throats and noses of a large number of workers suffering from sore throats and coryza. This was done under the supervision of Dr. M. R. Brady, and cultures were made in his laboratories. The cultures were taken on to warmed fresh blood agar slopes, and the tubes were carefully kept warm until they were actually placed in the incubator. By this method a greater variety of organisms was found in the cultures than in controls which were allowed to cool, or which were taken on other culture media.

In the manufacture of the mass autogenous vaccine, scrupulous attention was paid to the smallest bacteriological details and technique. If a luxuriant growth of the micro-organisms was not obtained on a twelve-hour culture, fresh cultures were taken so as to avoid repeated subculturing, which would have tended to attenuate the organisms, and therefore to lessen the potency of the vaccine. In sterilizing the vaccine the minimum amount of heat was used, all suspensions being killed in thirty minutes at 60° C. The total amount of antiseptic in the vaccine was 0.5 per cent. phenol in 0.9 per cent. sodium chloride: thus the possibility of extensively damaging the structure of the micro-organisms was reduced to a minimum. It was essential to give accurate doses in so potent a vaccine, so the strength of every micro-organism contained in the vaccine was estimated by counting on a Thoma-Zeiss haemocytometer.

It is interesting to note that the influenza bacillus was found in a large number of cases where these precautions were observed, but was not found in cultures taken from the same patients in tubes which had been allowed to cool between the taking of the culture and the placing of the tube in the incubator. The organisms found were:

Staphylococcus (mixed), *Streptococcus haemolyticus*, streptococcus, *Micrococcus flavus*, pneumococcus, *Micrococcus tetragenus*, Friedländer's bacillus, *Bacillus influenzae*.

and from these the vaccine was made up. The first dose consisted of 50 millions of the mixed staphylococcus and 5 millions of each of the other organisms in 1 c.cm. The second dose was four times the first, and the third dose was ten times the first. It has to be admitted that the increase in dosage was somewhat steep, but this was

done in order to enable a large final dose to be given and at the same time to avoid the inconvenience which would have been caused to the patients had it been decided to work up to the maximum dose by an increased number of injections. Very few of those inoculated developed a general reaction ; in such cases intermediate doses were administered with only a 50 per cent. increase over the previous dose. A very small percentage required the full number of five doses. In the few cases in which a reaction occurred, there was already existing some degree of mild, acute, or chronic catarrh. By paying careful attention to the importance of already existing catarrh, it should be possible to avoid general reactions.

Persons subject to "colds" and influenza are to a large extent the "carriers" of the coryza epidemics. The micro-organisms which they pass on have often an increased virulence. They are the most susceptible to infection, and have the lowest resistance. In our efforts to reduce epidemics, these cases must be immunized against their own micro-organisms, and, for a few years, should be prophylactically immunized against the prevailing coryzal infection.

The result of this inoculation on absenteeism for catarrhal conditions was as follows. The percentage of inoculated persons who lost time owing to catarrhal affections was 35.294 ; while the corresponding percentage of uninoculated persons was 51.625. There is little doubt that the beneficial effect of inoculation would be much more obvious were it not for the efficacy of the treatment applied to the uninoculated who subsequently became infected.

Treatment of Catarrhal Conditions

Patients reporting sick were divided roughly into two classes:

1. Those in whom severe symptoms had developed. These cases were subdivided into: (*a*) those where the onset of symptoms occurred less than thirty-six hours before the patient reported sick ; (*b*) those where the onset of symptoms occurred more than thirty-six hours before the patient reported sick, and where he had neglected to seek medical advice in the early stages of the infection.
2. Those presenting only mild symptoms.

The cases classified as severe were those with a temperature of over 100°, pulse over 120, headache and severe coryza, or physical signs of involvement of the lungs or bronchi. The mild cases were given simple symptomatic treatment—for example, quinine, aspirin, expectorants, etc.

The treatment for cases classified as severe was determined by the duration of the symptoms. Patients who gave a history of thirty-six hours or less were given 1 c.cm. of S.U.P. 36 intramuscularly. Injections were made at first into the upper border of the trapezius muscle, but later into the deltoid, as injections at this site produced less discomfort.

Cases which were of more than thirty-six hours' duration were given 2 c.cm. hypodermically of a polyvalent antibody. The preparation which gave the most satisfactory results is that sold under the name of "antibacsyn." This injection was repeated daily in a number of patients who were able to continue at work, but who still presented some symptoms.

It is to be noted that the patients treated with S.U.P. and antibacsyn were such as, in the ordinary course of events, might be expected to be disabled from one to three or more weeks. In a few instances in which the patient "did not believe in injections," the refusal of treatment was followed by absence from work of from two to six weeks, and many of these cases were certified as acute bronchitis, lobular and lobar pneumonia.

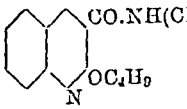
The absenteeism among the severe cases so treated was 8.958 days, while the absenteeism among the mild cases amounted to 3.536 days. In other words, the severe cases so treated lost less than half a day more than the very mild cases which were given simple symptomatic treatment. One may conclude, therefore, that in S.U.P. 36 for early cases, and in antibacsyn for later cases, two valuable agents are available for combating the enormous loss of efficiency which catarrhal conditions impose on the community.

Conclusions

Prophylactic inoculation showed a definite reduction in the incidence and severity of catarrhal illnesses. This reduction is to some degree obscured by the successful use of S.U.P. 36 and antibacsyn in the treatment of the uninoculated—S.U.P. administered within thirty-six hours of the onset of the symptoms and antibacsyn administered after this period—which very substantially reduced the absenteeism from acute catarrhal conditions.

I must express my thanks to Dr. Brady for his invaluable advice and for his assistance in the preparation of the vaccines.

THE PHARMACOLOGY OF PERCAINE



BY

M. C. G. ISRAËLS, M.Sc. AND A. D. MACDONALD, M.A., M.B.

(From the Department of Pharmacology, University of Manchester.)

While considerable clinical experience of percaine has been reported in this country, in the *British Medical Journal* and elsewhere, both as a local anaesthetic (Lake and Marshall,[1] Walker,[2] Popper[3]) and for spinal anaesthesia (Howard Jones[4]), no report of the pharmacology of this drug has, to our knowledge, appeared from a British laboratory. In view of the discrepant findings of Continental workers (Uhlmann,[5] Lipschitz and Laubender[6 7]), and of the increasing use of local and regional anaesthesia in surgery, a further investigation of percaine, and a comparison of it with the more established members of the group, seemed desirable.

Percaine is a quinoline derivation—the hydrochloride of the diethylethylenediamide of α-butyloxycinchoninic acid.

It is manufactured at Basle, and the first publication of its properties was made in June, 1929, by Uhlmann.[5] It is available in crystalline form, and is colourless, odourless, and easily soluble in water or normal saline, but is readily precipitated by alkali. The makers' claims—that it can be heat-sterilized without loss of strength, and that it can be combined with adrenaline—have been confirmed. Sterile solutions are stable, retaining full activity for several months at least. We have had some evidence that solutions which have not been kept under aseptic conditions lose their activity in a relatively short time.

The following experimental investigations have been carried out, in the hope that the value of the new drug might be fairly assessed.

Intradermal Wheal Test on the Human Subject

Solutions of various strengths in 0.9 per cent. NaCl were injected intradermally, always using 0.5 c.cm. for a test. The sensation of pain was tested by the application to the skin of a pin-point suitably mounted. Tests were directed to determine (*a*) the minimal concentration required for anaesthesia as compared with novocain, and (*b*) the duration of the anaesthesia afforded by any given

concentration The results are given in tabular form, showing (1) the drugs used by themselves, and (2) with adrenaline as an adjuvant. It will be seen (1) that the minimal effective concentration of percaine is about one-fortieth of that of novocain, (2) that 0 05 per cent percaine produces anaesthesia for longer than 1 per cent.

TABLE I

Drug	Concentration (per cent)	Duration of Anaesthesia in Minutes	
		(1) Without adrenaline	(2) With addition of adrenaline, 0 002 per cent
Percaine	0 003	0	(60)
	0 012	0	130
	0 06	0	240
	0 025	35	240
	0 05	70	420
Novocain	0 12	0	(?)
	0 25	0	150
	0 50	6	220
	1 00	25	270

Note—Adrenaline alone is probably responsible for the anaesthesia in parentheses

novocain, (3) that when both are mixed with adrenaline 0 002 per cent, 0 05 per cent percaine and 1 per cent. novocain produce anaesthesia of equal duration in the skin—nearly five hours.

Blocking of the Nervous Impulse in the Frog's Nerve-Muscle Preparation

This test is mainly of academic interest, being valuable for the comparison of the ability of anaesthetics to block impulses in motor nerve fibres About 1 cm of the nerve of the ordinary sciatic-gastrocnemius preparation is immersed in a solution of the anaesthetic, and the duration of immersion in which conduction is just suspended is determined The two hind limbs of the frog yield two similar preparations, so that two drugs can be fairly accurately compared for their activity By this test percaine is about seven times as efficacious as cocaine

Anaesthesia of the Rabbit's Cornea

This test is of importance for its application to ophthalmological practice in particular, and the anaesthesia of mucous membranes in general. The method prescribed by Sollman[3] was used The conjunctival sac

TABLE II—*Anaesthesia of the Rabbit's Cornea*

Percaine

Dilution (per cent)	0 0.2	0 0.5	0 010	0 017	0 025	0 05
Duration (minutes)	0	0	10–15	45–60	90–120	over 120

Cocaine

Dilution (per cent)	0.2	0.5	1 0	2 0
Duration (minutes)	0	7–10	15–20	30 45

is flooded with the solution under test for one minute, and the corneal reflex is stimulated at intervals until it returns The durations of anaesthesia thus obtained for various concentrations of percaine and cocaine are given in Table II

It will be evident that percaine is efficacious in about one-fiftieth of the concentration of cocaine which abolishes the reflex No adrenaline was added to the solutions in any of these experiments.

Experimental Spinal Block in the Cat

In two of three experiments in which novocain and percaine were alternately introduced by lumbar puncture into the spinal theca of a chloralosed cat, it was found that percaine abolished active reflexes, such as the knee-jerk, in a dosage of about one fortieth of that of novocain, and the anaesthesia, as tested by the abolition of these reflexes, lasted three or four times as long—for example, two hours with 0 5 mg of percaine, as against half an hour with 20 mg novocain. This is quite in accordance with the claims made for percaine by Howard Jones [4]

Toxicity of Percaine

This is obviously a matter of great importance, for percaine, like other local anaesthetics, falls short of the ideal in being a distinctly toxic drug. We have carried out estimates of relative toxicities by the lethal dose following (1) subcutaneous injection into guinea-pigs, and (2) intravenous injection into cats, using paralysis of respiration as an end-point. The details of this second method, which we have elaborated in order to get a more accurate measurement of relative toxicity—two drugs being compared on a single animal—will be published elsewhere [5]

The results of the guinea-pig method indicate that percaine is about twenty-five times as toxic as novocain and three times as toxic as cocaine, by the cat method the corresponding figures are fifteen and two respectively, and in the authors' opinion the latter figures are the more reliable. Taking these figures we can form, as in Table III, an estimate of the relative efficiencies of the three drugs.

TABLE III—*Relative Efficiencies*

Relative Efficiencies	Percaine	Cocaine	Novocain
(a) In intradermal wheal	10	1	6
(b) In rabbit's cornea	25	1	useless
(c) As spinal anaesthetic	3	—	1

The efficiency of a local anaesthetic for any purpose is determined by the ratio of the active or adequate dose to the toxic dose

Discussion

The figures of Table III suggest that percaine and novocain are of the same order of efficiency when used for subcutaneous anaesthesia, and the difference in favour of percaine for spinal anaesthesia is probably not as great as it appears to be, for the action of novocain intrathecally can be limited and intensified and prolonged by giving it in a viscous solution. On the other hand, for local application to mucous membranes percaine is quite the most efficient local anaesthetic we have so far investigated. As far as can be seen, no injurious results follow from continued application of the drug to mucous membranes—even to a membrane as delicate as the conjunctiva. Thus 0 05 per cent percaine was applied once a day for fourteen days to the eye of a rabbit without any noticeable ill effects The fact, noted by Uhlmann,[5] that much higher concentrations may cause corneal opacities is of toxicological rather than of ordinary practical interest

From these experiments we conclude that for infiltration anaesthesia, in view of its considerably greater toxicity, no great advantage can be claimed for percaine as a substitute for the novocain-adrenaline combination to which the surgeon is well accustomed Occasionally, where adrenaline action is to be avoided, percaine would supply an adequate duration of anaesthesia without interfering significantly with the local circulation and percaine is a cheap substitute for novocain, especially since it is

effective in considerable dilution. For mucous membranes, on the other hand, we agree with Popper[3] that percaine is a most promising addition to the surgeon's pharmacopoeia, and may well pave the way to the abandonment of cocaine.

THE MECHANISM OF CEPHALIC PRESENTATIONS

BY

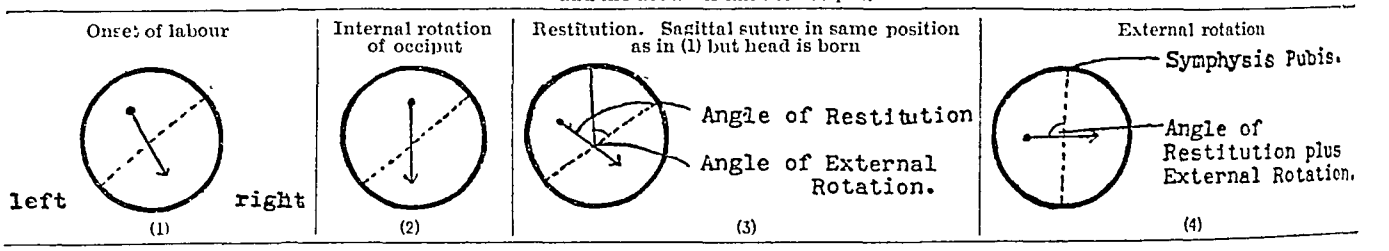
C. ALLAN BIRCH, M.D., M.R.C.P., M.M.S.A., D.P.H.

SENIOR MEDICAL REGISTRAR, LIVERPOOL ROYAL INFIRMARY; LATE HOUSE-SURGEON, LIVERPOOL MATERNITY HOSPITAL

The main features of the mechanism which the head goes through, when in the pelvis, in cephalic presentations are easily understood; but the rotations which occur after the head is born are usually ill described. This is probably because these rotations are not very important in practice. A clear conception of them is nevertheless desirable, especially for the student. Two phases of mechanism of the head may be considered:

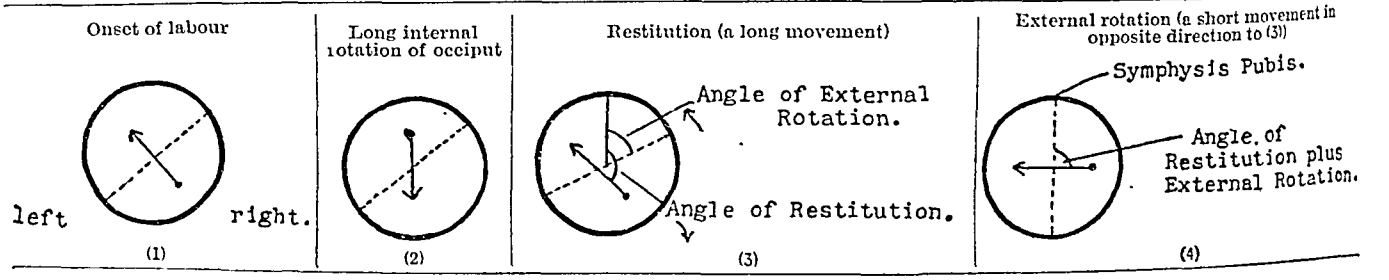
1. In the pelvis—consisting of engagement, descent with internal rotation,* and extension at the outlet, causing disengagement or birth of the head.
2. Outside the pelvis—consisting of restitution and external rotation.

These two movements of the head after it is born are commonly ascribed to untwisting of the neck and rotation of the shoulders respectively. Their exact extent is not usually described, and is, in fact, hard to determine. Observation is difficult, since the movements may occur rapidly. The exact extent of these rotations is not of great importance in practical midwifery, since the head is already born when they occur, and subsequent difficulty is relatively uncommon. Nevertheless, an accurate mechanical conception of the movements is of assistance, since it tends to a clear understanding of the whole mechanism of cephalic presentations, provided that the limitations of such mathematical conceptions are realized.



The following generalizations are helpful in a consideration of the exact nature of the movements of the head after disengagement.

1. Restitution is equal in degree but opposite in direction to internal rotation.
2. Restitution plus external rotation together make a right angle.



When rotation of the head occurs in the pelvis, the shoulders as a rule do not undergo much rotation, and for the present purpose we shall consider that, apart from descending, they remain fixed and do not rotate. As soon as the head is born the twist on the neck is undone, and the head slips back to the position it occupied when engagement occurred. This movement is called restitution, since the head is restored to its normal position in relation to the shoulders. In anterior positions restitution is slight, occurs through one-eighth of a circle, and is difficult to observe. In posterior positions internal rotation of the occiput occupies three-eighths of a circle; according to our rules restitution ought to be a movement of corresponding extent, though of opposite direction; and external rotation, a small movement through one-eighth of a circle in the reverse direction to restitution, so as to bring the bisacromial diameter and the sagittal suture at right angles.

MECHANISM OF L.O.A. (Face Looks to Right).

The circle represents the pelvis seen from above. The dotted line is the bisacromial diameter. The arrow is the sagittal suture, and the dot at its tail the occiput.

MECHANISM OF R.O.P. (Face Looks to Left).

Internal and external rotations are sometimes described as being in opposite directions in all cases. While it is true that the rotations of the head occurring in the pelvis and outside the pelvis are in opposite directions, it will be seen from the diagrams that in posterior positions it is the part of rotation outside the pelvis called restitution which is opposite in direction to internal rotation; and that the true external rotation—that is, that due to rotation of the shoulders—is actually in the same direction as internal rotation of the head, though only of small degree. The foetal neck is capable of considerable torsion, but the head and shoulders cannot, in posterior positions, be considered as independent of each other. Internal rotation of the head takes place when the foetus is low in the pelvis, by which time some rotation of the shoulders will also have begun. For the sake of clearness this need not upset our mechanical conception, and for teaching purposes it is simpler to

* The term "internal rotation" means rotation in the pelvis and does not refer to the direction of rotation.

remember the above rules and to modify them in any given case as necessary. The fundamental idea of this mechanical conception is based on the fact that the bisacromial diameter and the sagittal suture are at right angles, both at engagement and after delivery of the head. Any rotations of the head and shoulders, whether considered together or separately, must result in these two diameters being at right angles again; and the rotation of the head which occurs after it has undergone restitution is really due to the rotation of the shoulders still in the pelvis. These two rules are illustrated in the diagrams. In posterior positions of the occiput rotation of the shoulders and head may occur together, though it is simpler to consider them as occurring separately. In face presentations the submentobregmatic diameter should be considered instead of the sagittal suture.

In conclusion, it should be remembered that in this description the foetal head and pelvis have been regarded as fitting each other accurately. Careful observation in cases in which the head is small shows that the movement called restitution may not occur, and sometimes the occiput, when the head is born, turns in a direction opposite to that which purely theoretical considerations would lead one to expect.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

MÉNIÈRE'S DISEASE WITH MYELOGENOUS LEUKAEMIA

The following case would seem worthy of record as an example of Ménière's disease associated with myelogenous leukaemia, and in view of the remarkable response to x ray treatment.

CASE HISTORY

The patient, a married woman aged 37, first attended the out patient department of King's College Hospital on May 14th 1930, complaining of an attack of giddiness three weeks previously, accompanied by deafness and tinnitus on the left side, which had persisted. She also complained of headaches for about six months, and of menorrhagia and epistaxis.

On examination the spleen was found to be enlarged and firm extending one inch beyond the mid-line and below the left iliac crest. The liver was enlarged two inches below the right costal margin.

The blood picture on May 29th, 1930, showed red blood corpuscles 2,125,000 per c.mm., haemoglobin, 42 per cent., colour index, 1·0, leucocytes, 655,000 per c.mm.—polymorphonuclears 37·2 per cent., eosinophils 5·2 per cent., basophils 0·8 per cent., lymphocytes 2·8 per cent., large mononuclears 0·4 per cent., myelocytes 53·6 per cent.

The retinae showed a typical leukaemic retinitis, the disk margins being very indefinite and the whole fundus pale and oedematous. The veins were much increased in calibre and were extremely tortuous. There were a few haemorrhages in both fundi. Aural examination revealed Bárámy box to right ear—shout not heard in left. Weber: fork → right. Rinne: right—air conduction greater than bone conduction; left—no air conduction, bone conduction just heard in right ear, very slight loss of air and bone conduction in right ear. Caloric test: left, negative.

Treatment by means of arsenic by mouth and x rays to the spleen and long bones was commenced on June 4th, 1930, and the blood picture rapidly improved. After three months' treatment the patient was very much better, the spleen considerably smaller and softer, and the retinae greatly improved.

Blood count September 2nd, 1930: red blood corpuscles 4,860,000 per c.mm., haemoglobin, 66 per cent., colour index, 0·67, leucocytes, 11,200 per c.mm.—polymorphonuclears 72·4 per cent., eosinophils 4·4 per cent., basophils, 1·6 per cent., lymphocytes 14·8 per cent., large mononuclears 1·6 per cent., myelocytes 5·2 per cent.

Shortly after this the patient went away for some six months, and had no x-ray treatment. When seen again in April, 1931, she was still fairly well, but the leucocyte count had increased to 96,800. Throughout the year that this patient has been under observation the condition of the left ear has remained unchanged.

I beg to acknowledge my thanks to Dr. A. C. D. Firth for his permission to publish this case.

L. A. H. SNOWBALL, M.B., M.R.C.P.,
House Surgeon, Hampstead General Hospital, late House Physician, King's College Hospital.

"IDIOPATHIC" SPONTANEOUS PNEUMOTHORAX

Examples of the above condition are still frequently described as great rarities and of obscure pathogeny. I have seen, and have collected records of, a number of such cases, and should like to have an opportunity of repeating concisely my view of their probable pathogeny. Nearly all of them get better rapidly without any special treatment, exceptionally, two or more attacks may occur in the same individual. The cause is, I believe, mostly the rupture of a minute superficial emphysema-bulla (just below the visceral pleura) adherent to the parietal pleura—resulting from a healed miliary tubercle. On the other hand, the tuberculous process may be still more or less active (still containing living tubercle bacilli); and naturally, therefore, there are exceptional cases intermediate between "idiopathic" spontaneous pneumothorax and tuberculous spontaneous pneumothorax. The only difference (according to my view) between the tuberculous and the "idiopathic" cases is that the former are connected with still more or less virulent tuberculous foci (containing living bacilli), whereas the latter are connected with healed (non-virulent, sterile) lesions, but lesions of both kinds may exist side by side in the same individual. I have given a bibliographical appendix on the subject at the end of the first Mitchell Lecture before the Royal College of Physicians (that is to say, as it was published by Lewis and Co., 1921). It is clear that, if my view be correct, any apparently (and, in fact, really) healthy individual may, for all one can tell, develop suddenly an "idiopathic" spontaneous pneumothorax, because anyone may have an adherent emphysema-bulla (resulting from a healed miliary tubercle) ready to rupture on any unusually sudden respiratory movement.

The same explanation applies to extremely rare cases of "idiopathic" spontaneous haemopneumothorax.

London, W.1. F. PARKES WEBER.

SURVIVAL AFTER PROSTATECTOMY

In the *Journal* of October 17th Mr. W. S. Dickie reported the case of a patient who lived twenty-three years after the operation of prostatectomy and died at the age of 93.

The expectation of life after this operation is a point of considerable importance. Prostatectomy as applied to simple enlargements of the gland has only been in use in this country for some thirty years, and, so far as I know, no figures have been published recently to show what effect it has on the normal duration of life. It may therefore be of interest to recall some of the operative results obtained by Sir Peter Freyer, whose first cases were performed in 1901, and whose successes really established it as a sound surgical procedure.

The data have been obtained from the careful notes made by Freyer on 129 of his cases, preserved along with his collection of prostatic tumours in the pathological museum of St. Peter's Hospital for Stone. Of these 129 cases there are "follow-up" histories in 82 instances.

Out of these 82, the patients who lived for ten years or longer have been selected, numbering 26 in all, but, as many others were noted by the surgeon as being in good health at periods shorter than ten years, the number coming into this category was probably much higher.

The fact remains that at least 31 per cent. of the 82 patients lived for ten years or longer. Their respective ages and duration of life are shown in the accompanying tables. It will be noted that 7 patients attained the

Reports of Societies

X-RAY DIAGNOSIS OF DISEASES OF THE CHEST

The first scientific meeting of the newly constituted Section of Radiology of the Royal Society of Medicine was held on November 20th, under the presidency of Professor J. WOODBURN MORISON, when *x*-ray diagnosis of diseases of the chest was taken as the subject for discussion.

Dr. STANLEY MELVILLE, in opening, said that he regarded all intra-thoracic disease as an essentially clinical study from start to finish. Radiology afforded the most certain and unmistakable evidence of all the ancillary aids to diagnosis, and was the eye of the clinician in internal medicine. He believed that in the early diagnosis of pulmonary tuberculosis definite infiltration could be demonstrated on the *x*-ray film as soon as there was any clinical evidence, that when physical signs were present it might be assumed that the initial stage was passed, the film usually showing far more evidence of disease than was obtainable by means of physical examination, and that finally, if it were a matter only of radiographic examination versus physical signs, the former would be the surer guide, although, fortunately for the patient, the skilled clinician had many more tests at his disposal than percussion and auscultation. In pulmonary tuberculosis the vast majority of infections were by inhalation, and in the adult most investigators regarded all further invasion of the lung as a reinfection. There was much in favour of the theory of reinfection. This view took note of the acquired reaction of the previously infected person—the allergic state, so to speak. In the infant the usual course, depending naturally upon dosage and resistance, was either an acute caseating broncho-pneumonia or a localized broncho-pneumonia in any part of the lung—most commonly in the lower lobe. The clinical evidence might be slight; the local area in the lung might entirely clear up, and at the same time the tracheo-bronchial glands might react, and the story come to an end. On the other hand, the glands might remain in a state of caseation and the second stage be reached where the glands became the principal factor. The future depended upon whether the glands opened into the bronchus, the blood vessels, or the lymphatics. There was another very interesting condition in association with inflamed glands—namely, lymphatic gland tuberculosis, in which, in addition to the definitely outlined glandular opacities, a condition of involved parenchymata might be found. An inflamed tuberculous gland in the hilum gave rise to a local perifocal inflammation. This condition had been studied by many observers, and was known under many names. Such appearances might be very evanescent, persistent, or recurrent; clinical symptoms might be slight or absent, but the infant responded positively to tuberculin. This was evidence of infection, though not of an active lesion. So-called "peribronchial phthisis" the speaker regarded as a most sad heresy, but it was a heresy for which, he feared, radiologists were responsible, because in early days they allowed themselves to be overwhelmed by the massive shadows to which they ascribed pathological significance. On such a diagnosis many hundreds of able-bodied men, chiefly Russians and Poles living in the East End of London, had escaped military service. The fact that linear striation in the lung was composed, not only of bronchi, but of blood vessels, lymphatics, connective tissue, and so forth, seemed to have been entirely overlooked. A simple chronic bronchitis might result in thickening or fibrosis of the bronchial wall with enlargement of the hilar glands, and, if there had been ulceration in the bronchus, streaky sputum and peribronchial fibrosis. It was true that in the case of chronic tuberculous infection of the lung thickening of every tissue, including the bronchi, was found, but because thickening of the bronchi was seen and there might be a little haemoptysis, there was no justification for such a term as "peribronchial tuberculosis." Passing on to consider lung abscess, Dr. Melville discussed the common causes, and said that the picture was well known. He emphasized the value of lipiodol appearances. As to benign neoplasms, it had to be remembered that they were benign only in the pathological sense. In course of time, however benign a neoplasm might be, it would kill by pressure. He had seen several fibromata, weighing as much as 6 lb., which pushed everything in front of them, causing very great distress and eventually death. All benign neoplasms were extra-pulmonary, and as they grew the lung was pushed in front of them. This in itself was an aid to diagnosis. The commonest benign tumour was the fibroma, which grew almost invariably from the posterior thoracic wall, and very often from the head of a rib. It reached quite a large size without causing symptoms, the appearance being that of a well-rounded opacity, showing up in marked contrast to the surrounding lung. Of the other neoplasms he referred only to teratomata. These were anterior in position, not so readily made out as fibromata, more irritant, often irregular in shape, and causing adhesions to the lung tissue, from which they were not readily separated. The diagnosis was made by the perfectly straightforward evidence of a picture in the lateral

plane, in which the growth was seen to have its origin from the mediastinum in the anterior part

Dr. PETER KERLEY said that the commonest malignant condition of the lungs was primary bronchial carcinoma, which was apparently increasing. This apparent increase was due to improved methods of diagnosis, and particularly to improved radiographic technique One of the difficulties which beset all workers on lung malignancy was the means of finding a classification acceptable to everyone He proposed, therefore, to make use of the simplest radiological classification—namely, the two forms in which the disease was most often seen. the lobar or pneumonic form, and the hilar form. The former was due to a combination of growth and collapse ; in the hilar form there was growth without collapse, and this might be readily converted into the lobar or pneumonic form In the lobar form the contraction of the lobe, as evidenced by displacement of the fissure upwards, was first noted by radiologists, and led to a revision of the pre-radiological idea that neoplasms of the lung increased the thoracic contents The thoracic contents were always diminished by primary lung cancer On closer study of a radiograph of lobar carcinoma it would be observed that the opacity was most dense near the root, and diminished in intensity towards the periphery There was no doubt that carcinoma of the lung was the commonest cause of bronchial stenosis and of phrenic paralysis The nerve was at first compressed, and later infiltrated, by the glands A less well-known disturbance associated with carcinoma of the lung was compression or invasion of the vagus The resulting effect was disturbance of the cardiac rhythm, not to be distinguished ante mortem from malignant invasion of the heart muscle Much more often, abdominal symptoms resulted from vagal irritation in the thorax, the commonest being complete or partial gastrospasm, while in rarer cases there might be spasm of the lower end of the oesophagus Very rarely a lung cancer compressed the oesophagus directly and gave rise to vomiting Pleural effusion as a complication of lobar pneumonia was the bugbear of the radiologist, for it masked nearly everything Circumstantial evidence must be looked for, and fortunately this was forthcoming in most cases The weakest point in the mediastinum was at the level of the third thoracic vertebra, and it was here that one looked for evidence of excessive pressure when, for example, a pneumothorax was being carried out The possible association of pleural effusion with phrenic paralysis must be mentioned The diaphragm, when paralysed, completely lost its tone An effusion of any size loading an atonic diaphragm quickly depressed it The visualization of large bronchial or mediastinal glands was a most valuable diagnostic point, and one of considerable significance, as it contraindicated surgical intervention The chief conditions simulating lobar carcinoma were tuberculous pneumonia, syphilis, and aneurysm, but it should not be forgotten that a combination of aneurysm and growth was possible Secondary infection of pneumonic carcinoma by pus-forming organisms was frequent, but it was exceptional for such infection to obscure the other radiographic signs of neoplasm Occasionally the signs of abscess might obscure those of carcinoma In the absence of obvious pointers to malignancy, one sign which might be relied upon was that simple lung abscess was invariably surrounded symmetrically by an area of congested lung tissue. With regard to the so-called hilar form of the disease, this was seen as a dense opacity around the root of the lung. It was easier to diagnose than the lobar or pneumonic type, because there were few other lung conditions causing similar appearances Pleurisy seldom complicated this type of disease until the patient was moribund A sudden transition from the hilar type to the pneumonic type was not uncommon In this type of disease, obstruction of the superior vena cava took place earlier than with the pneumonic type Lymphadenoma invading the lung and an unusual form of pulmonary syphilis were the only conditions simulating the one under discussion If pulmonary syphilis manifested itself as a hilar opacity, there was always gross interstitial emphysema in the neighbouring lung tissue. That emphysema in itself was against carcinoma

Dr F. G CHANDLER said that the value of *x* rays in the diagnosis of thoracic disease could not be exaggerated, but in early tuberculosis he doubted whether it was the quickest method, though it would certainly show the extent of the disease as nothing else would. He had understood Dr. Melville to say that infiltration appeared as soon as the clinical manifestations He agreed that it would appear before the physical signs, but the first few tuberculous nodules, while they would not cast a shadow, might, he believed, produce tubercle bacilli in the sputum, and in his opinion that was the earliest method of diagnosing tuberculosis with certainty. With regard to the apparent increase of malignant disease, his view was that this was the result of improved methods of diagnosis If the increase was a real one, it was the most terrible menace experienced in this generation There were many possibilities of error in diagnosing malignant disease , he had seen malignant disease described as phthisis, abscess, fibrosis, bronchitis, syphilis of the lung, fungus infection (because not infrequently there was a superadded saprophytic infection), empyema, bronchiectasis, aneurysm, and cancer of some other part of the body. Dr. Kerley had mentioned the difficulties that might be caused by fluid These might sometimes be overcome, not by ordinary methods of aspiration, but by the substitution of air or oxygen for the fluid, which would give a good *x* ray picture Taken in conjunction with other signs, negative findings were of just as much value in radiography as positive findings He doubted whether to-day any abdominal operation for malignant growth was justifiable before an *x*-ray picture of the chest had been taken It was of no use to operate on a malignant mass in the stomach when there was a carcinomatous growth in the chest

The PRESIDENT, taking up the question about the recorded increase of cancer, referred to the figures lately given by Dr Dunlop, Registrar-General for Scotland, in which he showed that there was no real increase of cancer at the present day Practically the cancer incidence was stationary, with the one exception of cancer of the breast. He attributed the statistical increase in the lung, prostate, and other cases definitely to radiological and improved pathological methods of examination.

Dr MAURICE DAVIDSON made a few generalizations as a pure clinician. In non-malignant conditions one of the great difficulties in radiological diagnosis lay in the comparative absence of anything like a recognized standard of normality. He had always regretted that there was not a sufficient recognition of the need for a standard of control by normal radiology of the chest The term "normal" must necessarily be an arbitrary one, but the difficulty of a normal standard in radiology lay in the wide variation which existed between the different radiological appearances compatible with the condition described as health He wished a series of chest radiographs could be taken of persons of different ages, occupations, and sexes, who could be described as being in good health He also stressed the insufficient amount of correlation between the clinical and radiological aspects of disease Out of ten people who insisted in theory upon the need for co-operation between the clinician and the radiologist only one insisted upon it in practice Over the term "lung abscess," which included a variety of

conditions differing considerably in their pathology and morbid histology, there was still a good deal of confusion. Lung abscess might be diagnosed clinically and radiologically in cases where it was merely the outward and visible expression of some other underlying condition—for example, new growth. He believed that there was a real increase in primary carcinoma of the lung, and cited certain post-mortem records from German and Swiss clinics which showed that since 1910 the proportion of lung cancer to total cancer had gone up from 2 or 3 per cent. to 13 per cent.

Dr. R. E. ROBERTS discussed the subject from the point of view of the professional radiologist. He agreed with Dr. Melville that *x* rays gave probably the earliest, and undoubtedly the most certain, diagnosis of tuberculosis, but in respect of malignant disease he felt that there was still much to be desired. At the hospital to which he was radiologist it was the custom of surgeons before operating on a carcinoma of the breast to send for a radiograph of the chest for exclusion of malignant disease, and it was rather disappointing, three or four months after a negative examination had been made and the patient had been operated on, to find that there was extensive malignant disease of the lung. It seemed to him that cases which were sent down to the *x*-ray department for a pre-operative opinion involved too great a responsibility for the radiologist, because, as a rule, these cases were not examined carefully by a clinician before operation. He also spoke of the difficulty of distinguishing between silicosis, silicosis plus tuberculosis, and silicosis plus malignant disease.

Mr. J. B. HUNTER, speaking as a surgeon, said that the surgeon's province was not, of course, in the finer diagnosis of tuberculosis of the lung; he had to deal, so to speak, with the darker shadows in the chest. But he felt that radiology could help enormously in the screening of tuberculous cases with a view to showing whether a phrenic evulsion should be done or not. It was surprising to find on doing a thoracotomy for malignant disease, where it was intended to introduce radon seeds, how shrunken was the lung, bearing out the well-known point that there was a tremendous amount of collapse surrounding the tumour, and that very often the radiograph in no way assisted in estimating the tumour size. With regard to abscess of the lung and the assistance given by lipiodol, the number of cases in which lipiodol was found to run into a lung abscess was almost negligible. Either the abscess itself, if it opened into the bronchus, opened posteriorly or lower down, or there was some kind of valvular arrangement which prevented lipiodol gaining entrance. Very often, with a diagnosis of tumour—fibroma or cartilaginous tumour—in the upper lobe, when one went into the question one found that there was a retrosternal goitre. It was quite a simple method of clearing up the diagnosis in such cases to screen the patient and ask him to swallow. Retrosternal goitres would always move when the patient swallowed, whereas no other tumour of the chest wall would do so.

Dr. R. A. YOUNG, after speaking of the value of *x*-ray assistance and the need for team work, supported strongly the protest Dr. Chandler had made against the statement that *x* rays might give the earliest indications of tuberculous disease. He was emphatic that the earliest indications were clinical, either symptomatic or from the presence of tubercle bacilli. The very earliest lesions were microscopic, but might be sufficiently definite to produce bacilli in the sputum. Radiologists should be careful how they put down miliary tubercle as an explanation of the shadows they saw, at any rate in the absence of some statement as to the clinical condition. He had had several cases in which a great deal of anxiety had been caused by an *x*-ray report in which the statement was made that there was extensive miliary disease in one or more lobes, when the patient was quite afebrile, and there was some other explanation of the shadows. He supported Dr. Davidson in his plea for more definite statements as to the standard "normal." He also wished that radiologists would produce a standard (not stereotyped) form of report. He pointed out the great value of *x* rays in demonstrating interlobar conditions, particularly interlobar empyema, and sometimes interlobar serous pleurisy. The strictly lateral *x* ray was of great value; often in localization it seemed almost more valuable than the stereoscopic *x* ray. With regard to malignant disease, he was an unrepentant believer in the idea that this condition in recent years had been greatly on the increase. In former days, although clinicians might have missed the malignant character of the disease, pathologists and morbid anatomists, who were extraordinarily able people, and under whom the great majority of suspicious conditions in the lung were sectioned, must have noticed such disease had it been present. He added a word about teratomata. These seemed commoner than might be expected. One hesitated sometimes to put the patient to the risk of an operation when they were found, but he was convinced that it was the right thing to do, both because the teratoma acted as a marked irritant to the lung tissue and other structures, and, moreover, because it could become malignant. He had recently seen a case in which a teratoma which was apparent in the *x*-ray picture taken ten years ago was allowed to remain, and recently, on operation, was found to have become malignant.

Dr. STANLEY MELVILLE, in replying, said the discussion had brought out the vital necessity for team work. With regard to the increase in the incidence of lung cancer, for twenty years he had never missed the opportunity of seeing every result of post-mortem examination at the Brompton Hospital, and he was quite certain that the morbid anatomist of twenty years ago would not have passed over the cases which were now being seen once or twice every week had they been present then. With regard to Mr. Hunter's remark about lipiodol, he had always regarded the non-entrance of lipiodol into the lung abscess as the greatest confirmatory evidence available. He had very rarely seen lipiodol enter a lung abscess. As to Dr. Young's remarks about the radiologist's reports, it had to be remembered that the radiologist had the most difficult task in medicine—namely, to talk intelligently in terms of shadows.

FILARIA BANCROFTI

A meeting of the Royal Society of Tropical Medicine and Hygiene, with the president, Dr. CARMICHALL LOW, in the chair, was held at the Tropical Diseases Hospital on November 19th.

Dr. HAMILTON FAIRLEY demonstrated the new filarial intradermal test on cases of *Filaria bancrofti* with elephantiasis, non-filarial elephantiasis, and Calabar swelling due to *Loa loa* infestation. The importance of this reaction in differentiating between the two forms of elephantiasis was shown. The new complement-fixation reaction for the diagnosis of the filarial group of diseases in man was also demonstrated, an alcoholic extract of the dog filaria (*Dirofilaria immitis*) being used as antigen. The group nature of the reactions was stressed, and it was pointed out that by means of these two tests it was now possible to detect filarial antibody in the circulating blood as well as in the cutaneous vascular endothelium.

Colonel CLAYTON LANE presented an important series of slides and photomicrographs dealing with the destruction of adult and embryo *Filaria bancrofti* in man, sent by Professor F. W. O'Connor from New York. The microscopical exhibit completely supported Manson's belief

in hyperfilariation, as many as fifty worms being found in a small group of temoral glands in one case.

Dr MANSON BAHR exhibited slides showing the uncoiling of the embryo of *Filaria bancrofti* within the egg capsule, and also specimens of adult *Filaria bancrofti* sent by Dr C Rowin of British Guiana An entomological exhibit from the School of Hygiene and Tropical Medicine included methods of study in atmospheric humidity in small places, by Dr P. A. BUXTON; methods of rearing blowfly larvae aseptically, by Dr. P P. HOBSON, and a survey of the climatic conditions lethal to insects of medical importance, by Dr. MELLANBY. Dr C AYRES showed two new laboratory instruments—the scopometer and the spectro-haemoglobinometer; while Dr ALDO CASTELLANI demonstrated an amoeba test as an additional method of differentiating certain bacteria. A third case of coenurus in man was reported by Dr. H A BAYLIS, and Dr TERTIUS CLARKE showed slides from a case of rheumatic carditis with Rickettsia-like bodies Dr CARMICHAEL LOW and Dr HAMILTON FAIRLEY presented pathological specimens from a case of gastro jejuno-colic fistula with megalocytic anaemia, while Sir LEONARD ROGERS showed a case of refractory sprue which had responded dramatically to hepatex P A F intravenously An exhibition of radiographs on liver abscess was shown by Dr MATHER CORDINER and Dr MANSON BAHR.

CONGENITAL DISLOCATION OF THE HIP

At a meeting of the Liverpool Medical Institution held on November 12th, with the president, Professor W. BLAIR BELL, in the chair, Mr BRYAN MCFARLAND read a paper on the problems of congenital dislocation of the hip

Mr McFarland said that in this disease the most difficult differential diagnosis was from late cases of suppurative arthritis of the hip in infancy (Smith's) *X*-rays, however, settled the question For cases of congenital dislocation over the age when closed reduction is advisable, there was a choice of two operative procedures osteotomy (Lorenz), or formation of a bony "shelf" above the false acetabulum Transient stiffness following closed manipulative reduction and plaster was, if anything, a good feature, and disappeared in about six to nine months Discussing young children in whom the dislocation was so severe that closed reduction was out of the question, the speaker suggested that the "arthritis" which often follows the alternative, open operation was not a real arthritis, but an atrophy due to pressure exerted on the femoral head by the pre-existing shortness of the soft tissues The "shelf" operation was described and discussed in connexion with cases having a very poor acetabulum with no roof In these patients reduction of the dislocation was easy, but retention impossible. Finally, Mr. McFarland demonstrated the principal feature of an ordinary manipulative reduction, and, to dispel any suggestion that the open operation was routine, showed a series of complete cures by the closed method. The communication consisted almost entirely of a cinematograph record of cases and operations, and was profusely illustrated with *x*-ray photographs

Mr T P MCMURRAY said that in his opinion the treatment of congenital hips depended upon one factor, and that was regeneration (or not) of the upper border of the acetabulum All cases of congenital hip should, if possible, be treated by closed manipulation, and if a recurrence of the dislocation took place the upper lip of the acetabulum should be re formed by means of a wedge-shaped lip which increased the depth of the socket and so prevented dislocation. As a result of this the lordosis disappeared and the pain and aching which usually came on in adult or old untreated cases of congenital dislocation was avoided The pain in an old case resulted from stretching of the ligaments of the hip-joint with the gluteal muscles over the acetabular head, and was not, as usually described, due to the formation of an arthritis If an opening was made near this tender area the head of the bone would be found quite free from any trace of arthritis.

BEGINNINGS OF URINARY DISEASE

Mr. ROBERT KENNON, in a paper on the beginnings of urinary disease, described how the commonest urinary symptoms of frequency, scalding, and dribbling may have very simple origins An overloaded bladder with subsequent atony could result from modesty, neglect, or excess of fluid intake, while renal symptoms might follow shortage of fluid intake, faulty dietary, excess of fruit, purgatives, and the hexamine compounds The atonic bladder required rest, and the development of cystitis could be prevented by two-stage micturition and bladder drill. In pyelitis arising from the usual stagnation or from blood-borne infection, alkaline diuresis might fail, unless the customary spasm was treated by large bougies and gradual vesical distension Two-stage micturition should be a routine for all patients in bed or attending ante natal clinics

Mr. C A WELLS asked the speaker what investigations had been made on his cases with a view to confirming the hypothesis on which the paper was based and excluding other conditions productive of stasis Such conditions were not uncommon, and would frequently be disclosed only by appropriate urological methods It seemed to him that the importance of these underlying anatomical or anatomico-physiological abnormalities was considerable in infections of the urinary tract. He instanced the well-known dilatation of the ureters in pregnancy, prostatic enlargement, and congenital and other dilatations of the ureters and renal pelves He found it stimulating and refreshing to have the subject approached from the aspect Mr Kennon had presented—one which seemed to have been neglected more on account of its very obviousness and direct simplicity than for any other reason

Dr HUGH SMITH drew attention to an apparent change in the bacteriology of urines from that of pre-war days. He considered that atypical coliform bacilli, non-lactose-fermenting in type, were much more in evidence now, and when present were difficult to treat by the drugs usually employed He pointed out the disadvantage of using alkalis only in the treatment of mixed urinary infections, and quoted, as an example, the mixed infection of *B coli* and *B. proteus*, which occasionally arises. When the urine was rendered alkaline *B. proteus* predominated, when it was brought back to an acid reaction by acid sodium phosphate, *B. coli* returned. He did not agree that vaccines were of no help in urinary infections Autogenous vaccines had a definite place in the treatment of such conditions, and good results were obtained with them. This was especially the case where there was no obstructive lesion, calculus, or new growth In differing from the view that *B. coli* were frequent in the urine of normal people, he remarked upon the large number of urines examined after being collected by catheterization Sterile cultures, or at the most a feeble growth of *Staphylococcus albus* of skin origin, were obtained, and this, coupled with the rare finding of *B coli* in numerous blood cultures examined, made it very unlikely that in health *B coli* found admittance to the kidneys by the blood stream and were excreted in the urine Further reference was made to the rarity of true staphylococcal infections of the urinary tract Coliform bacilli of various types were still the greatest offenders

Reviews

MENTAL DEFICIENCY

The book on *The Mental Defective*,[1] by Professor R. J. A. Berry and Dr. R. G. Gordon, was, so the preface states, written at the request of representatives of both the lay and medical publics, presumably with the object of instructing them in the subject of mental deficiency. If it be true, as the authors assure us, that not only does the number of people now called upon to handle defective children and various other forms of mental abnormality appear to be "in inverse proportion to their actual knowledge of mental deficiency itself," but also that, as regards brain physiology, even the medical man must be included in the category of the untrained, the urgent need for such instruction is indeed obvious.

How have the authors succeeded in their task? Parts of the book are good. For instance, the chapters on the evolution of brain and the making of mind afford useful short sketches of these subjects. The description of the chief psychological and physical defects of aments, if too incomplete to be of much value to the medical man, is nevertheless a short readable account, which may be of use to the lay public. The chapter on the social consequences of mental deficiency emphasizes the great importance of the subject to the community. Unfortunately, however, the book has grave faults. It contains too many dogmatic utterances and extravagant assertions, and some actual inaccuracies; there are also many important omissions, which seriously impair its educational value. For instance, it is not correct to say that prior to 1899 idiots and imbeciles were dealt with, if at all, under the Lunacy Acts. As a matter of fact, a special Idiots Act was passed in 1886, which enabled these persons to be dealt with under a different procedure and in special institutions, and many were so dealt with. It is erroneous to infer that there are places in which "drab time" is wasted "in inculcating the Saxon kings of England" upon low-grade defectives. Again, J. S. Bolton did not introduce the word "amentia" in 1912; nor does he apply it with "exactly the same meaning as the legal and popular 'mental deficiency.'" Bolton uses the term with a much wider connotation. It is incorrect to say that "it is the English tendency, especially of those working under the Education Act, to refer to higher grades of aments as 'backward' or 'retarded' children." The Education Act especially defines the mentally defective child as one who is *not* "merely dull or backward." The authors' dictum that the number of mental defectives in any English and American community "may not improbably be 15 or 20 *per cent.*" is unsupported by a shred of evidence. The authors define primary and secondary amentia in terms which are not only at variance with those generally recognized, but which are self-contradictory. They say, for instance, that primary amentia is due to causes operative on the *fertilized* ovum, and then they immediately say that most of these cases are due to defective germ plasm and are *hereditary* in origin. Indeed, there appears to be a similar confusion of thought as to the meaning of the term "mental deficiency" itself, for, whilst in some places the authors use this with the connotation recognized by the Mental Deficiency Acts, in others they use it to include a class of persons entirely outside the legal definition, but whom they do not define. Lastly, it is now well known that mental deficiency is no single clinical entity, but a state of mental incompleteness which may result from many different conditions. It follows that the recognition of the different clinical varieties is not only a matter of convenience, but one of necessity to a proper understanding of the subject. This book gives no account of these varieties; it does not even describe such a prevalent and distinctive type as mongolism.

A. F. Tredgold.

MICROBES AND ULTRA-MICROBES

The little book with this title[2] has as its object the introduction of the student of biology to the subject of filterable viruses and the related phenomenon of bacteriophagy. It is divided into three parts, the first of which is concerned with the bacteria and their variation. This is a clear and essentially orthodox account, which serves as a background to the main theme—the ultra-microbes and the Twort-d'Herelle phenomenon—which is dealt with in Parts II and III. The account of the filterable viruses is not so well done as that of the bacteria. It is marred by inaccuracies, such as the statement that the three antigenic types of foot-and-mouth disease virus become the same after passage through the guinea-pig, and that mouse sarcoma is due to a filterable virus. And in the list of virus diseases (p. 67) it is surely misleading to place psittacosis and rabies as virus diseases of man when they are essentially diseases of lower animals, human infection occurring as a pure accident. Further, we disagree with the inclusion of *Les Ultravirus et Formes Filtrantes des Microbes* in the list of books recommended for further study; its author has little first-hand knowledge of filterable viruses, and has made some gross errors in his account of them. The rest of the book is devoted to the bacteriophage, and the description of this phenomenon is clear, concise, and well balanced. In an appendix by G. R. de Beer the analogy between the bacteriophage and the gene is discussed, and there is a glossary of technical terms and an adequate index.

CLINICAL DIETETICS

Clinical Dietetics,[3] by Dr. Gauss, is distinguished from the very many other books which deal with the same subject, and which conform to much the same general type, by a certain vigour of style and clearness of expression, and by the fact that the author has enlivened it by the introduction of some interesting matter dealing with the historical aspects of his subject. The first chapter, for example, deals with the history of dietetics. Dr. Gauss admits, at the outset, that we have no information about the diet of *Pithecanthropus erectus*, the "primitive man" of Java, and very little about that of later types that lived during the Palaeolithic Age; his statements, therefore, are speculative—perhaps fanciful would be a better description. But they are entertaining to read. His discussion of the early history of deficiency diseases is distinctly interesting, and his brief sketch of Anson's (surely not Lord, but Sir John) ill-fated expedition is terse and picturesque. He might, perhaps, have mentioned that Sir John Hawkins is reputed to have known, at least two hundred years earlier, that lemons were good for scurvy. Equally interesting, and still more to the point, is the discussion of "kosher" food. The section might be read with profit by anyone interested in institutional dietetics.

A description of the principles of nutrition, and of the aspects of biochemistry which are most important to their

[2] *Microbes and Ultramicrobes.* By A. D. Gardner, D.M., F.R.C.S. With an appendix by G. R. de Beer, B.Sc. Methuen's Monographs on Biological Subjects. London: Methuen and Co., Ltd. 1931. (Pp. viii + 120; 21 figures. 3s. 6d. net.)

[3] *Clinical Dietetics.* By Harry Gauss, M.S., M.D., F.A.C.P., assisted by E. V. Gauss, B.A. London: H. Kimpton. 1931. (Pp. 490; 59 figures. 36s. net.)

understanding, is followed by a more detailed discussion of the dietetic requirements in various pathological conditions, with specific suggestions for menus. There are the usual tables of caloric values of foodstuffs, and of the details of the composition of different foods. Besides some common etymological inexactitudes there are one or two rather gross mistakes. The classification of vitamins seems almost wholly wrong—"water-soluble A" is written for "water-soluble B," and vitamin E is described as the "haematopoietic" vitamin. Apart from the fact that vitamin E appears to be associated with reproduction, it seems, at present, to be quite unjustifiable to classify pernicious anaemia as a "deficiency disease" in the ordinary sense. So far as our information goes—which is not very far—it would probably be just as suitably classified along with diabetes or cretinism. These errors are the more to be regretted in view of the great confusion in which the vitamin question at present stands. It seems a pity to classify insulin as a polysaccharide, as is done on page 66. Presumably "inulin" is intended.

PSYCHOPATHOLOGY

Motives and Mechanisms of the Mind[4] by Dr. E. GRAHAM HOWE, is intended to provide the medical practitioner with an introduction to psychopathology and applied psychology. The twelve chapters which comprise this book were originally presented as a series of post-graduate lectures under the auspices of the Tavistock Clinic, and have appeared in serial form in the *Lancet*.

The considerable incidence of psychoneuroses in the community makes it clearly impossible to relegate all such cases to the psychopathologist. The practitioner is the first person consulted, and the treatment of this class of patient is a responsibility that must rest in a considerable measure with him. It is sometimes said, Dr. Howe observes, that all general practitioners employ psychotherapy in the treatment of their patients, but, he adds, it is difficult to understand the word being aptly applied to any treatment which does not involve a knowledge of the pathology of the disorder and the reason for the method which is used. It is perhaps regrettable that psychopathology cannot yet be presented as a compact and uniform body of knowledge, but at the same time there are now generally admitted to be certain unconscious mechanisms that are responsible for the development of psychoneurotic symptoms, a knowledge of which enables the practitioner to employ psychotherapy with understanding, and often with success. This book by Dr. Howe would appear to be a very useful introduction to the study of the psychoneuroses. It requires and merits careful study, and will meet the needs of both the general practitioner and also those who are proposing to specialize and those who are preparing for a diploma in psychological medicine. The frequent references to concrete cases do much to assist the reader in grasping the general principles which it is the aim of the author to outline.

Dr. Howe has devoted the greater part of this work to a description of the underlying processes which are held to be responsible for the development of psychoneurotic symptoms, and he does not describe in detail the various forms of psychotherapy. This is no doubt the best method of approach to his subject, since it is only when the pathology of morbid mental states is appreciated that treatment can be said to have that precision and direction which is essential. The author does not overemphasize the possibilities of mental treatment. He regards it as inevitable that the practice of psychotherapy should always fall short of the preaching of psychopathology, but considers that the next few years may see a great advance upon our present methods of healing. This book may be recommended to the medical practitioner, who can scarcely fail to find it both interesting and helpful.

[4] *Motives and Mechanisms of the Mind.* By E. Graham Howe, M.B., B.S., D.P.M. London: The Lancet Limited. 1931. (Pp. xiii + 260; 8 diagrams. 10s. 6d. net.)

PROBLEMS OF MEDICAL PATHOLOGY

Professor CLERC and his eleven collaborators have provided their listeners, and now their readers, with twelve excellent discourses on problems of medical pathology.[5] This series of lectures, it should be explained, is a complementary course given to young graduates and others in Paris at the end of the summer session. The volume under review contains the lectures given in June, 1930, by such well-known teachers as Aubertin, Brulé, Chabrol, Laroche, and Pasteur Vallery-Radot. Each has lectured on a subject in which he is an acknowledged authority, and all the subjects are topical and essentially practical. Professor Clerc, the editor, opens with a critical review of the whole pathology and clinical results of thrombosis of the coronary arteries, with full references to American and British writers. The second lecture, by Aubertin on agranulocytosis (absence of granular leucocytes), is of particular interest. The introduction of this term is comparatively recent it was first used by Schultz (W.) in 1922, to describe a peculiar clinical syndrome occurring in women of middle age. The main symptoms and signs of this peculiar disease are severe ulceration of the throat and pharynx, high fever, frequently jaundice, and asthenia. Death not uncommonly ensues. Pathologically, leucopenia with an almost complete disappearance of the granular cells in the entire bone marrow is the characteristic feature. The erythroblastic tisues are undamaged, and there is neither anaemia nor reduction in the number of circulating red corpuscles. This is the pure Schultz type of agranulocytosis, but, as Aubertin and R. Levy showed in their well-known monograph (1928), there are other varieties of the same disease associated either with severe anaemia of the red cells or with the haemorrhagic diathesis. This peculiar syndrome has scarcely been recognized in this country, so that Aubertin's chapter is well worthy of notice. Other lectures are on such topical subjects as the alkali reserve of the body, coeliac disease, infective jaundice, basal metabolism; a striking article is contributed by Pasteur Vallery-Radot, on anaphylaxis as a problem in practical medicine.

GUY'S HOSPITAL REPORTS

The third quarterly instalment of the *Guy's Hospital Reports*[6] contains six articles: the first is the continuation of Sir William Hale-White's analysis of the past volumes, and deals with the period 1896 to 1908, during which a considerable amount of laboratory research was a prominent feature in the articles. Dr. J. A. Ryle writes in an attractively thoughtful vein on "The physician as naturalist," a title borrowed from the late Sir William Gairdner's Presidential address to the British Medical Association at Glasgow in 1888. Of the other four articles, which deal with special morbid conditions, two stand out in well-deserved prominence. The account by Dr J. R. B. Hern of ulcerative colitis is on the lines of a monograph, and should long serve as a source of reference on a disease the recognition of which, since 1875, is so largely due to

[5] *Problèmes Actuels de Pathologie Médicale.* Par A. Clerc et al. Paris: Masson et Cie. 1931. (Pp. 332; illustrated; 40 fr.)

[6] *Guy's Hospital Reports*, vol. 81 [vol. II, fourth series], No. 3, July, 1931. Edited by Arthur F. Hurst, M.D. London: The Lancet Limited. (Pp. 253-378. 36 figures. Annual subscription £2 2s.; single numbers 12s. 6d.)

Sir Samuel Wilks, Sir W. Hale-White, and Dr. Arthur Hurst, leading physicians to the hospital in successive generations. In an equally well-illustrated contribution Dr. C. F. Cosin reports in detail a case of osteitis fibrosa cystica with a cystic adenoma of a parathyroid, and analyses twenty-three other cases of hyperparathyroidism in association with multiple cysts in the bones, hypercalcaemia, a low plasma phosphorus, and an increased excretion of calcium. He points out that the study of active extracts of the endocrine glands has led to the recognition of new morbid conditions; for, just as the use of insulin and the production, by its inappropriate administration, of hypoglycaemia has been followed by the recognition of spontaneous hypoglycaemia due to hyperinsulinism caused by an adenoma of the islands of Langerhans in the pancreas, so has the use of Collip's parathormone been followed by realization of the association of parathyroid adenoma with the excessive mobilization of calcium and cystic changes in the bony skeleton. In both instances removal of the adenoma causes a dramatic return to normal, which usually progresses to a state of diminished glandular activity. In a short note on the condition of the teeth in a case of parathyroid tumour, Mr. Rushton shows that the teeth are not affected in the same way as the bones. Dr. R. L. Waterfield records a case of lead poisoning with symptoms delayed for twenty-four years.

NOTES ON BOOKS

The fine monograph on cholera[7] by Professor G. SANARELLI, director of the Institute of Hygiene of the University of Rome, deals, as its subtitle indicates, with the epidemiology, pathology, bacteriology, prophylaxis, and treatment of the disease. The appearance of the book is opportune, as no recent work on the subject has appeared either in Italy or in any other country. It is divided into three parts. The first contains seven chapters, devoted respectively to the geography and history of the disease, the clinical aspects, morbid anatomy, bacteriology, experimental action of the cholera vibrio, researches on the supposed toxin of cholera, and the pathogenesis of the disease. In the second part the epidemiology of cholera is fully discussed in all its bearings, including the predisposing and exciting causes, bacteriological diagnosis, the carrier question, specific prophylaxis, and treatment. The third part deals with the modes in which cholera is spread by pilgrims, and the various methods, internal and international, of control. A bibliography of the author's articles on cholera contributed to French and Italian journals is appended.

In our review of the eleventh edition of Howell's *Text-Book of Physiology* (November 14th, p. 903) it was said that the appearance of new editions of this useful book was an annual event. The publishers, Messrs. W. B. Saunders Company, remind us that, as a matter of fact, an interval of three years has elapsed between the appearance of each new edition since 1915.

Dairy practice is daily becoming more and more scientific, and the increasing use of milk and milk products as foods must also increase the interest of the medical profession in the subject. Accordingly the appearance of a new edition of *Dairy Bacteriology*[8] by Professor ORLA-JENSEN is opportune. This is a textbook—not a treatise—which deals with the bacteriology of milk from the point of view of the dairyman. It does not attempt the consideration of diseases which may be carried by milk, apart from a brief review of such organisms as may be excreted by the cow herself. Nevertheless, it contains much of interest and importance for the medical bacteriologist and the public health official, dealing as it does with cleaning and production of milk, normal and abnormal flora, preservation and treatment for direct consumption, grading of milk, and so on. It is admirably translated by Paul Arup, and should be in the hands of all interested in milk and milk production.

The transactions of the seventeenth annual conference of the National Association for the Prevention of Tuberculosis,[9] which was held at Margate in June, have now been published. The volume contains the full text of the opening speeches on various aspects of the prevention and treatment of tuberculosis in the child, and a summary of each discussion. Sir Robert Philip, in his introductory address, emphasized the importance of detecting tuberculosis in the early years of life, before the health was undermined; subsequent speakers, including Dr. Opie of Philadelphia, described the lines on which investigation should proceed and preventive treatment be adopted. The volume affords a handy summary of present-day activities in an important branch of clinical medicine.

A further volume of ten brochures, Nos. 250 to 259, has been issued by the International Labour Office in connexion with its encyclopaedia, *Occupation and Health*. These brochures relate respectively to ironing and ivory; kapok; lithopone; mental hygiene in industry; occupational diseases (historical review); occupational poisonings; naphthylamine; wool (disinfection); medical inspection of factories; metallization by pulverization; and methyl acetate. The volume is obtainable from the London office of this organization, 12, Victoria Street, S.W.1.

PREPARATIONS AND APPLIANCES

A TRIPLE-FLOW SUPRAPUBIC URINAL

Messrs. JOHN BELL AND CROYDEN have incorporated several features in the appliance illustrated herewith, to which they give the name "Arnold triple-flow suprapubic urinal." A kidney-shaped celluloid cap contains three outlets, so arranged that, no matter in what position the patient may be reposing, complete drainage is effected. Provision is made not only for drainage by catheter, but also for the removal of any urine which may pass between the catheter and the abdominal walls. All three outlets are connected with a rubber bag fitted with a non-return valve, which obviates any back flow. A special disk fitting holds the catheter in any desired position.

With this apparatus it is claimed that all urine is immediately passed into the rubber bag; the patient may lie in various positions without fear of urine collecting; various sizes of catheter may be used; all parts can be removed and sterilized. An easily detached adjustable belt is fitted.

PSEUDO-EPHEDRINE

For the benefit of readers of the annotation headed "Ephedrine and pseudo-ephedrine" in the *British Medical Journal* of November 14th (p. 906), Messrs. Burroughs Wellcome and Co. (Snow Hill Buildings, E.C.1) announce that they issue pseudo-ephedrine "Wellcome" brand as well as ephedrine "Wellcome" brand.

British Medical Journal

SATURDAY, NOVEMBER 28th, 1931

THE FUTURE OF PAEDIATRICS

It may seem strange to us in England that Dr. C. Anderson Aldrich, chairman of the Children's Section of the American Medical Association, should have thought it worth while to devote his address at the annual meeting of that association to the question whether paediatrics ought to survive as a specialty or disappear as having fulfilled its purpose. Unless we altogether misread the signs of the times, the medical profession of our country is not in any doubt as to the value of the special study of the diseases of children. Of recent years this branch of medicine has certainly increased its professional standing. Professorships have been established in it, more recognition in qualifying examinations has been accorded to it, a new journal dealing solely with research work in it has reached its sixth year of publication, and, whereas there used to be few physicians who limited their practice entirely to children, there are now a good many. To all appearances the subject of paediatrics with us is well established, flourishing, and full of promise. Nevertheless, Dr. Aldrich's question may well lead us to review the position. Does the development in paediatrics which we are now witnessing proceed from the pressure of the growth and expansion of medical science, or does it result merely from economic pressure in the strictly honourable business of earning a living?

Dr. Aldrich, we are glad to say, seems to have no doubt that paediatrics has won for itself a position which in the public interest should be maintained, and he defends his view largely by delineating problems still waiting solution in connexion with the health of children. Much may be said on this score; and, were this all, the future of paediatrics would still be in a strong position, for we feel persuaded that some of the questions propounded by Dr. Aldrich will persist to vex the profession so long as children continue to grace this world. But there is also another side to the picture, which is recognized by Dr. Aldrich—namely, the benefit that has accrued to general medicine by the special study of disease in children. Paediatric research has not only been of value in the study of diseases peculiar to children, but it has often thrown light on diseases of adults by exhibiting in their purest forms the same morbid processes as these occur in early life. Examples of this fact readily occur to the mind. To quote only one, we may put forward the aid given to Sir Archibald Garrod in the differentiation of rheumatoid arthritis and osteo-arthritis by the description of the former disease in children by Dr. G. F. Still. Sometimes, too, it has seemed as though progress in adult medicine has been retarded by insufficient attention to the same problems met with in paediatric practice. Acute rheumatism may be cited as an instance of this. How many years of patient endeavour has it required on the part of Dr. F. J. Poynton and others to get the profession away from the old conception of this disease as a form of arthritis, and to view it as a systemic infection whose worst efforts are concentrated in its attack on the heart? It is surely true to say that the special study of diseases of children forms one of the most interesting branches of medicine, because of the light it throws on the diseases of adult life, and not seldom on the personalities of adult patients; and if this is so, paediatrics could hardly put forward a more acceptable defence of its popularity.

Perhaps the problem of the necessity for the separation of paediatrics from general medicine is not quite the same in America as with us. With them there are many who not only study children's diseases exclusively, but confine their medical practice to child patients. In England, until after the war, such an arrangement was quite exceptional, and most of those who were specially interested and trained in children's diseases practised as general physicians; they by no means divorced themselves from general medicine, in which, indeed, they often were recognized leaders. Of recent years, for various reasons, more men and women have followed the other plan, and have become, in the strict sense of the word, "specialists" in children's diseases; and we have to consider if such an alteration in custom is good for paediatrics and of benefit to general medicine. It seems to have both advantages and disadvantages. Two advantages, at least, are very clear. In the first place, it leads to an increase in the amount of research undertaken in the diseases of children, and the support given by paediatric authors to the *Archives of Disease in Childhood*, established by the British Medical Association six years ago, is clear proof of the immense activity now prevailing in this field of medicine. Secondly, it probably stimulates work on the diseases and feeding problems of infancy, for this is a natural specialty, quite unavoidably separate from the medicine of older children and adults. Its disadvantages are, perhaps, more open to question. It might be said, for instance, that disease in childhood supplies rather a restricted field for the interests of a first-class intelligence, and that, with the exception of diseases of infants, the separation of paediatrics from general medicine is too artificial to be altogether good. But the real danger of such a cleavage seems to lie in the fact that it may lead to the loss by each subject of the illumination obtained from the other.

At the present time in this country the influence of fashion, the actions of the teaching hospitals, and the conveniences of medical education, all seem to favour the further development of paediatrics along the lines of a pure specialty. How far, should it persist, such a development will work out to the ultimate good of medical science probably depends on the degree of attraction which such a specialty may possess for physicians of the best type.

THE CLAIM OF MEDICAL CHARITY

Scarcely a month passes without some reference in these columns to the work of one or other of the two great medical charities—the Royal Medical Benevolent Fund, and the Epsom College Foundation. Christmas is drawing near, and we have before us a timely leaflet headed "The Royal Medical Benevolent Fund: What it is, and why it needs your support." This puts the case so well that we take the liberty of quoting from it at discretion, in the hope that greater publicity will both widen and strengthen the appeal.

The Fund exists to relieve suffering, poverty, and distress resulting from accident, ill-health, misfortune, or other calamity affecting medical practitioners, their widows, and dependants. How many members of our profession realize the number and urgency of the appeals that are made to the Fund? A prolonged and disabling illness, permanent incapacity, a premature death leaving a widow and young children with little or no provision, may be named among the more common experiences which bring applications for help. Even if it be allowed that in some instances provision for such contingencies might have been made by a policy of insurance, it must be remembered that the payment of one or more annual premiums in early medical practice may be an excessive burden. It is easy to be wise after the event, and the actual sufferer is not usually open to economic reproach. Pure misfortune compels an appeal for help. The widow or daughter of a medical practitioner, hitherto in an apparently secure position, is unexpectedly thrown alone on the world, and is quite without special capacity or skill. It is a hard experience, and, if health fails, disaster follows. The Fund has repeatedly to consider cases where from old age or illness the applicant, after some years' service as a housekeeper, companion, or teacher, is practically destitute but for the old age pension of £26 a year. At present the Fund cannot do more than add to this an annual grant of an equal amount. But it ought to be able to do more, and this is one of the reasons why it needs support.

While the provision of financial assistance is as a rule the main necessity, the Fund can at times help in other directions. It gives the sympathetic consideration which misfortune must always command. Further, it may, in particular instances, secure the co-operation and help of other philanthropic societies. Or again, it may help to complete the education of a fatherless child or the training of a youth. The Fund, in short, endeavours to act, not in a mere precise and formal philanthropic as [illegible] profession[illegible] of a new edition of *Dairy* Orla-Jensen is opportune. [illegible] treatise—which deals with the [illegible] the point of view of the dairyman [illegible] sideration of diseases which may be c[illegible] a brief review of such organisms [illegible] e cow herself. Nevertheless, [illegible] was estab-

[illegible]f. G. Sanarelli. Milan: Soc. [illegible] has always [illegible]. (Pp. xix + 561; 96 figures. [illegible] Professor Orla-Jensen, Dr.Phil [illegible] leading [illegible] P. S. Arup, M.Sc., F.I.C. [illegible]en to [illegible] A. Churchill. 1931. (Pp.

The procedure is as follows. Applications for grants from those in difficulties are received by the secretary, and investigation is made privately into the circumstances of the case. Every application must be supported by a subscriber and bear his signature, and be accompanied by letters of recommendation, of which one at least must be from a doctor. Whenever possible all applicants are personally interviewed. The application, together with a full report on the investigation of the case, is submitted to the Case Committee for its consideration and decision. No canvassing for votes is required, and thus the applicant is spared the publication of details of a private or painful character. Grants are voted to all deserving cases, and are for the period of one year, usually paid quarterly. Requests for the renewal of a grant are reviewed from year to year, and where the circumstances are unchanged the grant is renewed and sometimes increased. From the most urgent and most needy of those grantees who have reached the age of 60, the committee selects annuitants, to whom a fixed yearly sum is paid for life. Unfortunately, the lack of a sufficient income has hitherto compelled the Fund to fix the maximum annuity at £40, which is often quite inadequate. The grants are paid out of the income from subscriptions and donations; annuities are paid out of the income from invested capital.

Such, in brief, is the way in which the Royal Medical Benevolent Fund administers the limited sums at its disposal. These are difficult times, in which claims for assistance increase rather than diminish. The professional classes are heavily taxed, and the standard of life expected of them narrows the margin between economic comfort and discomfort perhaps to a greater extent than in any other section of the community. Yet we feel confident that practitioners of medicine, when they are fully aware of the urgent and just claims of medical charity, will not hesitate to support this good cause to the utmost of their ability.

STERILITY IN WOMEN

At the eighteenth meeting of the Scandinavian Surgical Association (Nordisk Kirurgisk Forening), held this year in Helsingfors, an address was given by the Norwegian gynaecologist, Dr. Harald Natvig, on the causes of sterility in women (also published as a supplement to *Norsk Magasin for Laegevidenskapen* for August). His material consists of 735 cases in which attempts were made to find the cause, or causes, of sterility. In a certain proportion of these a "probability diagnosis" was unavoidable, but in only 19 cases was it necessary to admit complete ignorance of the cause. A hypertrophic hymen and vaginismus were diagnosed in 15 cases, genital infantilism in 72, dysfunction of the ovaries in 119, genital infantilism *and* dysfunction of the ovaries in 56, cervicitis and endometritis in 33, retroversion of the uterus in 31, myoma of the uterus in 26, tumour of the ovaries in 11, and chronic pelvic peritonitis in 289. In this last group there were 89 cases of gonorrhoea, 74 of appendicitis, 61 of tuberculosis, and 35 of puerperal infection, as well as a certain

number of obscure infections. There were only 3 cases of impotentia coeundi in the male partner, but there were 22 cases of azoospermia, and 7 of oligospermia and necrospermia. These figures may well tend to underestimate the masculine factor in the problem of female sterility, for Dr. Natvig failed to examine the male partner in all but a fraction of his cases. He is convinced, however, that as far as Norway is concerned it would not be justifiable to accept a recent German estimate which attributes one-third of all sterile marriages to the husband's impotentia generandi (usually gonorrhoeal) or impotentia coeundi. According to the same German authority, if to this third another third be added in which sterility in the wife is due to gonorrhoea derived from her husband, there remains only one-third of all the cases of sterility for which woman alone is responsible. It will be seen from Dr. Natvig's material that gonorrhoeal pelvic peritonitis was diagnosed only in 89 cases, or 12.1 per cent. of the total, whereas in as many as 74 cases he associated the sterility with a previous attack of appendicitis. The observation that appendicitis should be responsible for 10 per cent. of all the cases is the more striking as in this material it numerically outweighed such well-known causes of sterility as tuberculosis and puerperal infection. The high proportion of cases in which the sterility yielded to treatment, and the high proportion of childless marriages in Norway (according to the census of 1920, from 10.95 to 15.56 per cent. of wedlocks in the towns are sterile), have led Dr. Natvig to conclude that some improvement in the quality of future generations may be effected by systematic, skilled, and selective handling of this problem in such a way that the sterility is cured only in otherwise normal persons.

THE HISTORY OF RECTAL SURGERY

Although it is to be supposed that genito-urinary specialists might claim pride of place for the antiquity of their branch of the art of surgery, having regard to the early records of the operation of circumcision, yet second place must assuredly be given to proctology, for it would appear that the history of surgery abounds with references to the operative treatment of fistula-in-ano throughout the ages. At the annual meeting of the proctological subsection of the Royal Society of Medicine on November 11th, Mr. W. S. Perrin delivered his presidential address on the history of rectal surgery, and traced the development of this branch of surgery from the fifth century B.C. Hippocrates was especially fluent on fistulae, and gave the first historical account of the method of curing fistula-in-ano by encircling it with a linen thread, which was daily tightened up ; in due course the track was laid open and a cure effected. Mr. Perrin pointed out that this long-forgotten method had been restored to virtue in a recent paper by Mr. Ernest Miles, who advocates it for the treatment of the submucous tracts in certain complicated fistulae. Four hundred years were to pass before Celsus wrote authoritatively on fistula, but it is doubtful how far Celsus himself was in fact an authority on the methods he described, as it seems more probable that he acted as a sort of Boswell to the numerous surgical Johnsons of the first century B.C. It is a far cry from Celsus to the fourteenth century, but John Arderne is the next notable landmark in this history. He was clearly a man of great intelligence and character, who not only described the treatment of fistula with much particularity, but also ventured to lay down in minutest detail the fees that should be charged, the amount varying according to the wealth of the patient. In the case of a rich man he insisted on a hundred marks, and made no suggestion of any reduction in amount in times of economic stress. Even in those days patients appear to have wandered from one specialist to another, although their wanderings took them further afield than the more limited peregrination of Harley Street and Wimpole Street usual in the twentieth century. Mr. Perrin gave an amusing account of how Arderne cured Sir Adam de Everyngham of a fistula which had resisted the efforts of "all the leeches and chirurgeons of Bordeaux, Toulouse, Narbonne, and many other places," for which cure he received "much honour and loving thought all over England." He was indeed a prophet in his own country, and for many years to come there was no surgeon in England who made so great a mark upon his age, or contributed so much to the art of surgery. Mediaeval England, however, relapsed into surgical obscurity, and much of the ordinary surgical work of the time fell into the hands of "journeyman specialists," who were generally well on their way before the end-results of their treatment had been established. Mr. Perrin did not refer to the itinerant quacks who existed by treating ruptures and fistulas and cutting for the stone. They must have been very numerous, and we know that the secrets of the methods they used were sometimes handed on from father to son for many generations. The lithotomists would appear to have been the aristocrats of this offshoot of the medical profession, and there is much interesting material to be found in the old records of their successes and far more frequent failures. Further pursuit of this sideline of the history of surgery would be of absorbing interest, and it is to be hoped that Mr. Perrin will find time to follow up so fascinating a subject. In the meantime, it is good for all of us to be reminded of the profound clinical knowledge and expert dexterity of the pioneers of our art at the dawn of surgical history, and to ask ourselves whether we should have managed half as well with the primitive appliances that they made shift to work with.

SPALLANZANI

Lazzaro Spallanzani (1729–99) is perhaps best known as a physiologist, but his favourite study was natural history, and in his own country he is honoured as a great naturalist. It was, more especially, his ambition to write a natural history of the sea in its physical and biological aspects, but his unceasing discoveries and the interminable accumulation of material left no time even for the commencement of the work. His friend Bonnet has stated that Spallanzani discovered more truths in five years than all the scientific academies did in half a century. His activities in this sphere are described by Giacomo Pighini[1] in an interesting and readable book, which gives an account of his travels on the shores of the Mediterranean, the Grecian Archipelago, the Bosphorus, the Black Sea, and in a large part of the inland regions of Europe. They were made

[1] Viaggi ed Esperienze marittime di Lazzaro Spallanzani. Di Giacomo Pighini. Prefazione di Guglielmo Bilancioni. Bologna: L. Cappelli. (L.40.)

with the object of collecting material for the study of marine fauna, and of making geological and mineralogical investigations on the spot. His collected specimens are preserved in the museum of the University of Pavia and have rendered that museum as celebrated as the Hunterian collection in this country. But, while describing Spallanzani's travels and discoveries, Signor Pighini has incidentally drawn a vivid portrait of the man himself, who appears, not merely as a distinguished scientist, but also as a student of philosophy, and an orator and writer of great distinction and wide culture. Above all, he gives the impression of being possessed of a singularly sound and acute judgement. We are apt to give Lyell the credit of familiarizing us with the habit of interpreting natural facts by natural means, but this appears to have been Spallanzani's habitual mode of regarding nature. This power of penetrating to the truth of natural phenomena, without the intervention of fanciful theories, is well exemplified in his physiological observations. Thus, when Needham propounded the theory of spontaneous generation on the ground that bacteria made their appearance in putrefying infusions, even after these had been boiled and confined in well-stoppered bottles, Spallanzani perceived that the theory was purely gratuitous. By the simple expedient of boiling the infusion in a hermetically sealed vessel he showed that no bacterial proliferation whatever occurred. Nevertheless, when once started, the theory held its ground almost to our own day, and it remained for Tyndall to dislodge it by a repetition of Spallanzani's experiment. Similarly with the theory that the spermatozoon was a diminutive human being, a homunculus, Spallanzani perceived that the ovum contained within it all the possibilities of development, given a suitable stimulus; but, his countrymen being shocked at his experimenting in this mysterious subject, he was forced to give up his researches. No less interesting, as illustrating his penetration, is his recognition of the existence of tissue-respiration and of the independence of the processes of oxygen-absorption and carbonic acid excretion, of which he furnished the proofs. Spallanzani was assuredly a man of whom Italy has reason to be proud.

N.S.P.C.C.

The annual report of the National Society for the Prevention of Cruelty to Children for 1930–31 confutes the notion that the recognized social services have cancelled the necessity for the society's vigilance. Cases of brutality have indeed increased, though the larger number reported may possibly be due to the fact that more have been brought to light. While there is evidence that the public is gradually realizing its responsibility in preventive work, cases of amazing callousness still occur, which reveal a reluctance on the part of observers to give early information. Last year, in England, Wales, and Ireland, 41,800 cases were reported in which the society's intervention was found to be justified. These involved the investigation of the circumstances of 105,800 children, or an average of 338 children every working day. Yet the society (founded in 1884) is still confronted by widespread ignorance of its activities. According to this report, there are tens of thousands of people who have never heard of its existence, and thousands more who do not know where to find an inspector. During the year the number of these officials has been increased to 259. Eleven women inspectors are responsible for sick and ailing children treated at hospitals in several of the large provincial towns. In reviewing the nature of the cases dealt with, the society comments on the prevalence of burns and scalds, mostly due to the accidents of children left unattended by thoughtless guardians. One branch reported that no fewer than fifteen cases of serious injury occurred in a single month. It has been found that this form of negligence can generally be dealt with by the exercise of some tact, and occasionally by assistance in providing safeguards. Under the heading of "public wrongs" it is pointed out that private schools without supervision can still mask the suffering of children; and the opinion is expressed that the major provisions of the Adoption Act should be made entirely compulsory. The society notes with satisfaction that the section of the Local Government Act, 1929, which places registration and visitation, under Part I of the Children Act, in the hands of the medical officers of counties and county boroughs, is working uniformly well. On the other hand, it regrets that as yet so little has been done to modify the isolation of canal boat children, though the abortive attempt to introduce legislation on the subject last year has not discouraged its supporters. Of evident value has been the unspectacular work carried on in the observation and assistance of ailing, convalescent, congenitally unfit, and abnormal children. In the London medical branch 516 new cases have been dealt with in the period under review, and many anxious but uninformed parents have been directed towards the treatment of their infants. It is clear from this modestly expressed report that a great deal of meritorious work has been done by the N.S.P.C.C. during the past year to release and secure the freedom of many innocent and helpless victims from their intolerable circumstances.

CATALYSIS AND MINERAL WATERS

The mode of action of the various mineral waters is still very obscure, and any attempt at explanation is welcome. At last week's meeting of the newly created Section of Physical Medicine of the Royal Society of Medicine Mr. A. Woodmansey described some experiments carried out at Harrogate on the catalytic action of the local waters. While the mass effect of mineral waters was being closely studied one particular aspect had been selected for certain *in vitro* experiments—namely, the catalytic action of the waters upon hydrogen peroxide. Expressing the equivalent of hydrogen peroxide decomposed in cubic centimetres of decinormal potassium permanganate, Mr. Woodmansey showed that the effect of iron water varied from 16.5 at the end of thirty minutes to 88 at the end of four hours. Control experiments with distilled water showed no such effect. On plotting a curve of the action of mineral water it was possible to arrive at an average hourly rate of decomposition. This figure was used as a "catalytic index" for any particular water. For iron water this index was 22. Exposure to air or boiling largely destroyed the catalytic action. "Crescent water" gave the highest index (29), and pure chalybeate water the lowest (4.9). Since iron and manganese are known to influence catalytic action it was decided to see if

any relation existed between the amount of these substances present in the mineral waters and the catalytic index. Preliminary investigations of the hydrogen ion concentration of mineral waters showed that such variations as are found had no relation to the catalytic index, nor did the iron content of the waters alone explain its variation index. Sulphur waters containing only a trace of iron gave indices varying from 7·5 to 17·6. Manganese, on the other hand, seemed to have some relation to catalytic action with one or two exceptions, such as Harlow water, where a minute quantity of manganese was associated with quite a moderate index (17·3). A further experiment tested the effect of adding a standard solution of catalase to mineral waters to see if any co-enzyme effect was produced. Definite inhibition was found in all but two instances, probably owing to a salt effect, but in the case of "crescent water" and "magnesia water" the combined effect was greater than the sum of the two separate effects—that is, suggestive of a co-enzyme action. Mr. Woodmansey put forward an attractive hypothesis to explain how the catalytic action of mineral water could produce effects in the human subject. He suggested that the metabolism of purin substances was definitely helped by such catalysts as were present, possibly by a co-enzyme action upon xanthine oxidase in the liver.

THE PRESIDENCY OF THE GENERAL MEDICAL COUNCIL

Since its formation in 1858, under the first Medical Act, the General Medical Council has had nine presidents—Sir Benjamin Brodie, Joseph Henry Green, Sir George Burrows, Sir George Paget, Sir Henry Acland, John Marshall, Sir Richard Quain, Sir William Turner, and Sir Donald MacAlister. The Council began its one hundred and thirty-fourth session on Tuesday, November 24th, and a full report of the address from the chair appears in the *Supplement* to our present issue. From this it will be seen that Sir Donald MacAlister, acting on medical advice, has resigned the high position to which he was appointed twenty-seven years ago, and which he has held with the greatest distinction. Sir Donald was first appointed to the Council as representative of the University of Cambridge on November 13th, 1889, and in 1908 he became the representative of the University of Glasgow. His whole period of service thus amounts to more than forty-two years. He succeeded Sir William Turner as President on November 29th, 1904. At the conclusion of public business on Tuesday the Council's regret at the relinquishment of office by one who has occupied a commanding position for so long was voiced by Sir John Moore. Later in the day, Sir Norman Walker, who has served continuously as Direct Representative for Scotland since January 1st, 1907, was elected to succeed Sir Donald MacAlister in the presidential chair. Sir Norman Walker has been President of the Royal College of Physicians of Edinburgh since 1929, he is consulting physician for diseases of the skin at the Edinburgh Royal Infirmary, inspector of anatomy for Scotland, and chairman of the Consultative Council for Medical and Allied Services, appointed by the Scottish Board of Health. During the war he was chairman and convener of the Scottish Medical Service Emergency Committee, and in 1905–7 he was chairman of the Science Committee of the British Medical Association. For many years he has sat on the dais by the side of the President, at meetings of the General Medical Council, and as Chairman of Business, as well as of the Examinations Committee, he has had much to do with the direction of the Council's affairs. He has visited the Indian universities on behalf of the Council, and his reports on his return influenced the Council greatly in dealing with the delicate situation regarding India which has arisen in recent times. The proposal to elect Sir Norman Walker President for the ensuing five years was made by Sir John Moore, and seconded by Sir Holburt Waring. After it had been carried, Sir Norman was congratulated by Sir Donald MacAlister and placed in the chair by him. Sir Norman Walker thanked the Council, and accepted the duty with which he had been entrusted.

PREVENTION OF BLINDNESS

On November 14th the general assembly of the International Association for the Prevention of Blindness was held in Paris under the chairmanship of Professor de Lapersonne. Representatives of the French Ministry of Health, the League of Nations, Great Britain, the United States, Belgium, Holland, Hungary, Italy, Poland, Spain, Switzerland and the Argentine were present. After the chairman had outlined the association's work for the past year and its plans for the future, a report on industrial eye accidents was read. The lack of provision for immediate treatment in these cases was commented upon, and a premium for workers seeking immediate attention was one of the proposed solutions of the problem. Mr. Bernard Cridland (whose article on the work of the International Association appeared in our issue of March 14th) suggested that before starting a propaganda campaign it would be as well to obtain uniform statistics on the causes of blindness in the different countries. The proposal was accepted after a speech by the Spanish representative, Dr. Marquez.

We regret to announce the sudden death, on November 20th, of Mr. A. W. Nuthall, F.R.C.S., surgeon to Queen's Hospital, Birmingham, and consulting surgeon to the Birmingham Children's Hospital, and of Dr. Frank Hawthorn, D.S.O., senior surgeon to the Newcastle upon Tyne Hospital for Sick Children.

The michaelmas meeting of the Society of British Neurological Surgeons is being held at the house of the Medical Society of London at the end of this week under the presidency of Mr. Donald Armour. On Friday, November 27th, at 10 a.m., Mr. Wilfred Trotter opens a discussion on spinal tumours; at noon Mr. Lambert Rogers exhibits a cinematograph film entitled "The skull plough"; in the afternoon there is a discussion on the pathology of the gliomas, and in the evening members dine at the Lansdowne Hotel. Saturday morning is devoted to operations at the London Hospital and a demonstration of cases.

The Buckston Browne prize and medal of the Harveian Society of London have been awarded to Mr. Cecil P. G. Wakeley, F.R.C.S., and Mr. Laurence O'Shaughnessy, F.R.C.S., whose essays on "The treatment of shock by intravenous therapy" were deemed by the president and assessors to be of equal merit.

THE BEGINNINGS OF THE CRIMINAL

LECTURE BY DR. LETITIA FAIRFIELD

At a meeting of the National Council for Mental Hygiene on November 12th, Dr. Letitia Fairfield delivered a lecture on the general subject of mental hygiene and the prevention of crime, especially from the standpoint of juvenile criminality. The presence of a lawyer in the chair, Mr. Herbert du Parcq, K.C., led her to remark on the parallel approach of the law and of mental hygiene to modern investigation of the criminal, both from the standpoint of those who had studied him in prison and from that of the psychological clinic.

Both legal experts in criminology and mental hygienists, Dr. Fairfield said, had laid emphasis on the same main factor—namely, the importance of early beginnings. A large percentage of prisoners began their criminal practices before the age of 21, and often as children. Juvenile courts in many places, notably in Chicago, showed that some of the gravest crimes amongst juveniles were linked with minor character defects which revealed themselves in the schoolroom. If crime was to be prevented, therefore, a start must be made, not with juvenile misdemeanour, but in the schoolroom, and even beyond the schoolroom, in the nursery. Modern hygienists and criminologists had also found themselves in agreement concerning the normality of the material with which they were dealing. When one tried to arouse interest in child guidance clinics one was confronted with the remark, "Ah, you are interested in the abnormal." This, of course, showed a total misunderstanding of the position. As the head of one child guidance clinic said, "The naughty child is as normal as the good child, probably more so.". The majority of behaviour and conduct difficulties, large or small, were superimposed by bad training or by external environment, or both, upon a perfectly normal mentality. Professor Cyril Burt, psychologist to the London County Council, had found this in studying juvenile criminals—namely, that they could be grouped, not as moral imbeciles so-called, nor as monsters of depravity, but around the normal instincts which everyone possessed. Various criminologists who had studied the adult criminal had come more and more to the same conclusion. Lombroso's discovery of an alleged innate criminal type, supposed to be condemned to a criminal career by the shape of their noses, their palates, or their fingers, had been discredited. Over-emphasis had been placed by others on the heredity of the child, but there was nothing in heredity which compelled the individual to develop in a certain direction, or placed a limit on what he did with the characters with which he was born. It had also been said that very large numbers of juvenile criminals were mentally deficient. Now that accurate tests were available, it was known that mental deficiency only obtained in a small proportion of criminals. Except for this small percentage, the defective did not become criminal, given reasonable education and training. Therefore it was important, both from the angle of mental hygiene and that of criminology, to bear in mind that there was an original basis of normality upon which to work.

What contribution, then, could mental hygiene make to the study and prevention of crime? To this question Dr. Fairfield replied that the main contribution lay in the formation of good citizens out of the average individual type. Crime came from failure to control both self and environment. The aim of mental hygiene was to teach man how to live at peace with himself and society, without conflict in his own mind or with his neighbours, and in command of the environment in which he was placed. Dr. Fairfield then entered upon a consideration of some of the requisites in the training of the child, which, if they were neglected or misunderstood, might cause the criminal habit to develop. The normal development of the child's love-life—its *libido*—might, for example, be interfered with at a very early stage owing to jealousy on the birth of another child. It was too often assumed that the child would accept a new rival in its parents' affections with perfect calm, sweetness, and unselfishness. If the situation were not carefully handled by the parent, the most violent conduct disturbances might ensue, issuing even occasionally in murder, and often in symbolic acts of destruction and retrogression to an infantile state. That was one way in which good habit formation might be interfered with and the child flung back for many years. Another emotional disturbance which had some effect, but which was not always recognized, was the disappearance of one or other beloved parent—by no means necessarily a worthy parent—as a result of death, divorce, or desertion. Very strange reactions sometimes ensued, taking the form, perhaps, of stealing or destruction, the child desiring to revenge itself for the outrage upon it and the loss of a parent who had been endeared. Again, real or imaginary harshness and repression had the same psychological effect on the child, leading to grudge-formations and emotional disturbance. The same was true of anything that encouraged an inferiority complex. For example, any irregularity of birth, which in cruder circles might lead to taunts or gibes, any physical peculiarity, especially a speech defect, might cause external training in habits, self-control, and moral ideas to fail, because the tormented child was unable to assimilate them. All these reactions showed first as mild misbehaviour, with nursery misdeeds, failure in control of simple reactions such as those connected with excretion, the destruction of other children's toys and clothes, and temper "tantrums." If the cause was not removed, or was aggravated, they might become fixed habit patterns, and continue, for other reasons perhaps, long after the original cause had been removed or forgotten. The cause might often appear grotesque, small, or absurd to the adult, but the child was arguing quite correctly from his own limited experience. Further, the child might be quite incapable of explaining what was the real and original cause which so upset his emotional development. It might be repressed or diverted, or associated with some covering incident. Dream interpretation of the simple overt dreams of the child was one method towards understanding, and another, introduced at clinics in London, was to watch the play activities of the child, especially with dolls and puppets. When children were left free from the guidance of their elders to work out situations with the material under their own hands, it was extraordinary how they would explain what was really worrying them, and very often the child would release its own complex, and find a solution for its own difficulties in sympathetic hands.

The annual report of the Victorian Bush Nursing Association records a marked increase in the number of obstetrical cases undertaken during the period ended June 30th, 1931. Closer co-operation with the medical profession has been a recent tendency, and during the year only 6 per cent. of the confinements were conducted without the help of a practitioner. The maternal mortality rate was 2.1 per 1,000 live births (State average, 5.4); stillbirth rate, 16.55 per 1,000 (State average, 31); neo-natal death rate, 13.91 per 1,000 (State average, 30.7). Sixty-five nursing centres are now in effective operation. They are all run on a co-operative basis, the householder paying an annual subscription of 30s. for nursing for himself and family. In Bush nursing hospitals weekly fees vary from £2 to £5.
